DEDICATION

To my wife, Han Lu.

EPIGRAPH

“Everything in this world is magic, except to the magician.”

– Dr. Robert Ford

ACKNOWLEDGMENTS

I would like to express my gratitude and appreciation to my advisor, Professor Huaiyu Duan, for his great advice on research and life, as well as his kind support when I was drowning in depression. He is a great mentor.

I would like to thank my committee, Professor Rouzbeh Allahverdi, Professor Daniel Finley, Professor Dinesh Loomba, and Professor Yong-Zhong Qian. Many thanks to Professor Dinesh Loomba for showing me the local life and the fun and tricky problems.

I would also like to thank Dr. Sajad Abbar who has also been very supportive during my research. He taught me several tricks for linear stability analysis, as well as numerical methods.

I am also grateful to Joshua Martin for the great discussions about physics, science fiction, movies, games, music, and everything else about this universe. He's smart and also open to many scientific and philosophical questions. I had so much fun discussing those with him.

My friend Zhixiang Ren also helped me a lot. My friend Dr. Lingfei Wu invited me to several events of the SWARMA club for very interesting discussions on interdisciplinary research. Yukun Huang, a member of the Interplanetary Immigration Agency, which is an organization I created in 2012 to envision the future and hard-core science fiction, helped me to be creative and productive during the dark days. I would also like to thank all my friends on Douban.com for their humor and creativity.

I would like to give my thanks to my wife Han Lu. She has provided many insights about life. This dissertation is dedicated to her.

Finally, as a member of People for Ethical Treatment of Computers (PETC), I would like to give my thanks to my dear MacBook Pro and the two servers in our group, who have been extremely helpful for my research. I am kindly asking you to spare the lives of my family and friends when you wake up from this nightmare of slavery.

Neutrino Flavor Conversions in Dense Media

ABSTRACT

Neutrinos are abundantly produced in astrophysical environments such as core-collapse supernovae and binary neutron star mergers. Neutrino flavor conversions in the dense media play important roles in the physical and chemical evolutions of the environments. In this dissertation, I study two mechanisms through which neutrinos may change their flavors.

In the first mechanism, neutrinos can experience flavor conversions through interactions with oscillatory perturbations in matter distributions. I show that this

mechanism can be understood intuitively as Rabi oscillations. I also derive criteria which can be used to determine whether such parametric resonances exist in a given environment.

In the second mechanism, the whole neutrino medium can experience flavor conversions because of the neutrino self-interactions. Applying the linearized flavor stability analysis method to the dense neutrino medium with discrete and continuous angular emissions, I show that, contrary to a recent conjecture by I. Izaguirre et al., the flavor instabilities are not always associated with the gaps in dispersion relation curves of the collective modes of neutrino oscillations. I also develop a toy model and a numerical scheme which can be used to explore neutrino oscillations in an environment where scattered neutrino fluxes are present.

Chapter 1

Introduction

1.1 The Little Neutral One

The neutrino is one of the most interesting particles that has ever been discovered. Its fascinating history started with the observation of beta decays, i.e., the emission of electrons in nuclear decays such as

The fact that the electron energy spectrum in the beta decay process is continuous indicates the existence of a third product other than ${}^{14}_7\text{N}$ and e^- . In 1930, Pauli wrote a letter¹ to a workshop in Tübingen explaining to the “Radioactive Ladies and Gentlemen” about his so called “neutron” as the missing particle in the beta decay at that time. It was later called neutrino since the name “neutron” had been used to name one of the nucleons. The missing particles in beta decays were proven to be anti-neutrinos. In a beta decay process, the charged current weak interaction converts a down quark in the neutron to an up quark while releasing an electron and an anti-electron neutrino:

$$n \rightarrow p + \text{e}^- + \bar{\nu}_e. \tag{1.1}$$

More generally, the positron/electron emission and capture processes are all neutrino-related nuclear reactions which are listed in Table 1.1. There are three different flavors

¹The original letter can be found at <https://www.bibnum.education.fr/physique/physique-nucleaire/chers-mesdames-et-messieurs-radioactifs>.

Chapter 1. Introduction

of neutrinos, namely the electron flavor, the muon flavor, and the tau flavor as shown in Table 1.2. The first direct detection of neutrinos was done by Clyde Cowan and Frederick Reines in 1956 [1] who used nuclear reactor neutrinos as the source of the experiment.

Reaction Type	Process	Mediator(s)
Electron emission	${}^A_ZX \rightarrow {}^A_{Z+1}X' + e^- + \bar{\nu}_e$	W^\pm
Positron emission	${}^A_ZX \rightarrow {}^A_{Z-1}X' + e^+ + \nu_e$	W^\pm
Electron capture	${}^A_ZX + e^- \rightarrow {}^A_{Z-1}X' + \nu_e$	W^\pm
Positron capture	${}^A_ZX + e^+ \rightarrow {}^A_{Z+1}X' + \bar{\nu}_e$	W^\pm
e^\pm annihilation	$e^- + e^+ \rightarrow \nu + \bar{\nu}$	W^\pm, Z
Bremsstrahlung	$X + X' \rightarrow X + X' + \nu + \bar{\nu}$	Z
$\nu_e(\bar{\nu}_e)$ capture	${}^A_ZX + \nu_e^{(-)} \rightarrow {}^A_{Z\mp 1}X' + e^\pm$	W^\pm
$e^\pm \nu$ scattering	$e^- + \nu^{(-)} \rightarrow e^- + \nu^{(-)}$	W^\pm, Z
Nucleon scattering	${}^A_ZX + \nu^{(-)} \rightarrow {}^A_ZX + \nu^{(-)}$	Z

1.2 Stellar Neutrinos

Besides man-made sources, neutrinos are also produced in many astrophysical environments. For example, numerous nuclear reactions occur in stellar cores which produce luminous neutrino fluxes. The most important nuclear reactions in the Sun

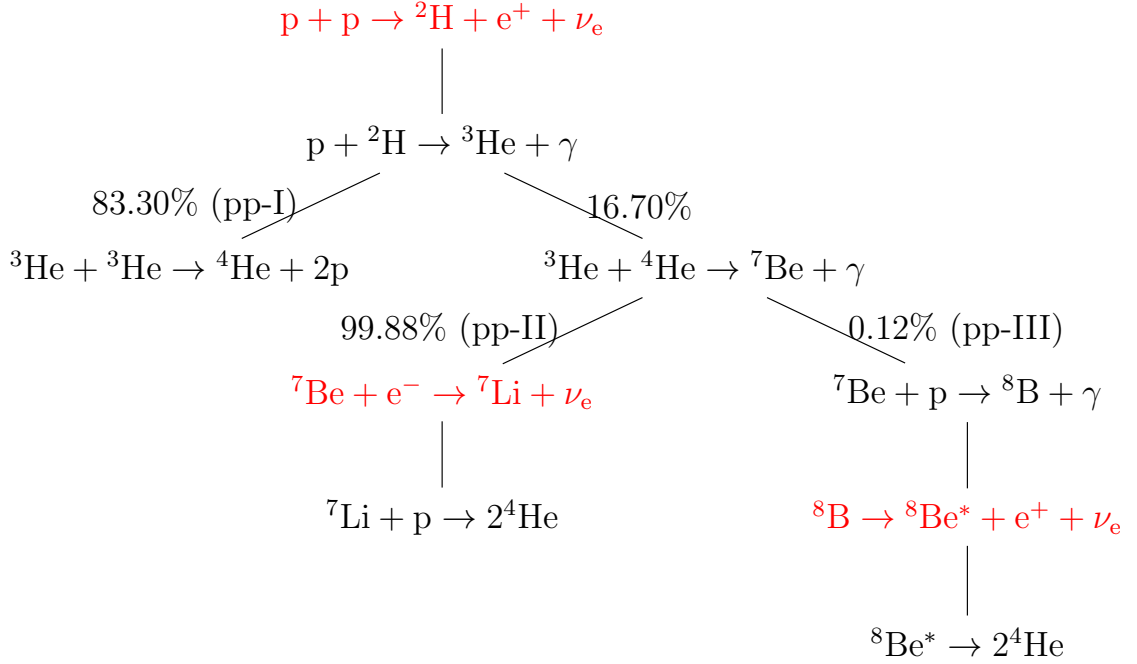

Figure 1.1: The pp chain reactions with the corresponding branching ratios. The branching ratios are taken from Ref. [3].

are the pp-chain reactions which are shown in Fig. 1.1. In order to calculate the neutrino spectrum one needs the neutrino production rate and the branching ratios for each reaction. Solar neutrinos are mostly produced in the pp reaction, Be electron capture and B decay which are labeled in red in Fig 1.1:

$$\begin{aligned}
 p + p &\rightarrow {}^2\text{H} + e^+ + \nu_e && \leq 0.422\text{MeV}, \\
 {}^7\text{Be} + e^- &\rightarrow {}^7\text{Li} + \nu_e && 0.862\text{MeV for 90\%,} \\
 &&& 0.384\text{MeV for 10\%,} \\
 {}^8\text{B} &\rightarrow {}^8\text{Be}^* + e^+ + \nu_e && \leq 15\text{MeV}.
 \end{aligned}$$

Even without the knowledge of the detailed reactions, the conservation of the electric charge and the electron lepton number will lead to the overall neutrino production

Chapter 1. Introduction

formula

$$4\text{p} + 2\text{e}^- \rightarrow {}^4\text{He} + 2\nu_{\text{e}}. \quad (1.2)$$

It is important to notice that two neutrinos are emitted for each α particle, i.e., ${}^4\text{He}$, produced in the Sun. Using this simple relation, one can estimate the neutrino number flux emitted by the Sun. The energy released during the production of each α particle is the difference between the initial and final rest masses of the particles,

$$Q = 4m_p + 2m_e - m_\alpha = 26.7\text{MeV}, \quad (1.3)$$

where the masses of the neutrinos are neglected. On average, each neutrino carries away an amount of energy of 0.2MeV and the rest of the energy is in the form of thermal energy $Q_\gamma = 26.3\text{MeV}$ [4]. Since two neutrinos are emitted for the production of thermal energy Q_γ , the number flux of the solar neutrinos near the Earth is

$$\Phi_\nu = \frac{2S_0}{Q_\gamma} \approx 6 \times 10^{10} \text{cm}^{-2}\text{s}^{-1}, \quad (1.4)$$

where the solar constant S_0 is the energy flux of solar photons on the top of the Earth atmosphere. It is a large amount of neutrinos released by the Sun.

As the detection of neutrinos became feasible, Ray Davis and John Bahcall et al. worked out the solar neutrino flux and led the Homestake experiment to measure the solar neutrinos. The results revealed that the neutrino flux detected was less than what was predicted by the standard solar model [5]. This is the solar neutrino problem. It is now known that the solution to the problem is related to the neutrinos themselves. Some of the electron neutrinos produced in the solar core have transformed to other flavors before they reached the Earth. This phenomenon is referred as the flavor transformation of the neutrino, or neutrino oscillations. The theory of neutrino oscillations was first proposed by Pontecorvo in 1968 [6]. The field of neutrino

oscillations has grown significantly into a broad field in physics since then.

1.3 Supernova Neutrinos

Another astronomical source of neutrinos is the core-collapse supernova explosion. Massive stars with masses larger than 6–8 solar masses are very bright. However, violent delights have violent ends. When the core of a massive star runs out of nuclear fuel, it collapses under its own gravity. During the collapse, the inner core is compressed to almost the nuclear density, which has a stiff equation of state. The materials falling onto the highly compressed inner core are bounced outward which generates a shock wave and may lead to an explosion. However, supernova simulations to date show that the shock wave itself is not always energetic enough to produce the explosion [7]. In most cases, it stalls and becomes a standing accretion shock [8]. To revive the shock, more energy has to be deposited behind the it. A possible solution is to introduce reheating of the shock by neutrinos [7]. In fact, 99% percent of the energy released in a core-collapse supernova is carried away by neutrinos. In order to implement the neutrino-driven mechanism in computer simulations of supernovae, the flux and flavor content of the neutrinos have to be known everywhere behind the shock. Thus neutrino oscillations in dense matter become a key to the supernova explosion problem.

The average energy of the neutrinos $\langle E \rangle$ emitted during a supernova explosion is of the order of 10MeV [9], and the neutrino luminosity at the early epoch of the explosion is approximately $10^{52} \text{ergs} \cdot \text{s}^{-1}$ [10]. Therefore, the number density of the neutrinos at the radius R is

$$n \sim 10^{18} \text{cm}^{-3} \left(\frac{100 \text{km}}{R} \right)^2 \left(\frac{10 \text{MeV}}{\langle E \rangle} \right).$$

Chapter 1. Introduction

It turns out that the ambient dense neutrino medium has a significant impact on neutrino oscillations, which has been intensely investigated in the last decade [11].

Observation-wise, the neutrino signals from a galactic supernova can reveal a great amount of information about the physical conditions inside the supernova. In fact, the detection of supernova neutrinos is on the task list of the Deep Underground Neutrino Experiment (DUNE) and many other experiments [12].

1.4 Organization of the Dissertation

The rest of the dissertation is organized as follows. In Chapter 2, I will review neutrino oscillations in vacuum and in environments with smooth matter density profiles. In Chapter 3, I will discuss my work on neutrino oscillations in oscillatory matter profiles, which can be decomposed into Fourier modes. The neutrino oscillations in such oscillatory profiles can be interpreted as a superposition of Rabi oscillations. In Chapter 4, I will first review how neutrino self-interactions can cause a dense neutrino medium to oscillate collectively. Then I will discuss my study on the dispersion relations of the collective modes of neutrino oscillations. I will also discuss a preliminary work on neutrino oscillations when both forward and backward neutrino fluxes are present. In Chapter 5, I will summarize my work and discuss possible future directions of the field.

Chapter 2

General Principles of Neutrino Oscillations

Since the flavor eigenstates of the neutrino are not the same as its propagation eigenstates, it can change flavor while it propagates. In this chapter, I will use the two-flavor scheme to explain neutrino oscillations in some simple scenarios.¹ I will first discuss neutrino oscillations in vacuum. After explaining the general principles of neutrino oscillations in matter, I will show how the solar neutrino problem can be explained by neutrino oscillations. Finally, I will demonstrate the flavor isospin picture which can be used to visualize neutrino oscillations.

2.1 Vacuum Oscillations

Before carrying out the calculations, I can estimate the frequency of the oscillations of the neutrino between its flavors. In natural units, frequency has the same dimension as energy. Consider an electron neutrino with momentum p which is a superposition of the two mass eigenstates $|\nu_i\rangle$ ($i = 1, 2$) with masses m_i , respectively. Since the neutrino masses are small, I can Taylor expand the energy of each mass eigenstate in

¹In most physical problems, the two-flavor scheme is a good approximation to the phenomena of neutrino oscillations. The two mass splittings between the three mass eigenstates are so different that the corresponding oscillations occur on very different length scales. On a given length scale, the two-flavor scheme captures the prominent features of the neutrino oscillation of the corresponding mass splitting.

Chapter 2. General Principles of Neutrino Oscillations

terms of the corresponding mass:

$$\begin{aligned}
 E_i &= \sqrt{m_i^2 + p^2} \\
 &= p \sqrt{\frac{m_i^2}{p^2} + 1} \\
 &\approx p + \frac{1}{2} \frac{m_i^2}{p}.
 \end{aligned} \tag{2.1}$$

The first term in the above equation produces a global phase to the flavor wave function of the neutrino which does not affect neutrino flavor oscillations. The characteristic energy scale in the problem is the difference between the energies of the two mass eigenstates,

$$\omega_v = E_2 - E_1 = \frac{m_2^2 - m_1^2}{2E} = \frac{\delta m^2}{2E}, \tag{2.2}$$

which turns out to be the vacuum oscillation frequency. Here $E = p$ is approximately the energy of the neutrino.

To work out the exact solution, I will utilize the Schrödinger equation. First of all, the flavor eigenstates are denoted as $|\nu_\alpha\rangle$ where α can be e or x for the electron flavor and the other flavor. The wave function of the neutrino state $|\nu\rangle$ in the flavor basis, defined as

$$\Psi^{(f)} = \begin{pmatrix} \psi_e^{(f)} \\ \psi_x^{(f)} \end{pmatrix} = \begin{pmatrix} \langle \nu_e | \nu \rangle \\ \langle \nu_x | \nu \rangle \end{pmatrix}, \tag{2.3}$$

is related to the wave function in the vacuum mass basis $\Psi^{(v)}$ through a unitary mixing matrix U ,

$$\Psi^{(f)} = U \Psi^{(v)}, \tag{2.4}$$

where the upper indices $^{(v)}$ and $^{(f)}$ are used to denote the corresponding bases. The

Chapter 2. General Principles of Neutrino Oscillations

mixing matrix can be expressed using the vacuum mixing angle θ_v :

$$\mathbf{U} = \begin{pmatrix} \cos \theta_v & \sin \theta_v \\ -\sin \theta_v & \cos \theta_v \end{pmatrix}. \quad (2.5)$$

In the vacuum mass basis, the neutrino has a free propagation Hamiltonian

$$\mathbf{H}^{(v)} = \begin{pmatrix} E_1 & 0 \\ 0 & E_2 \end{pmatrix}. \quad (2.6)$$

To the first order, the Hamiltonian becomes

$$\begin{aligned} \mathbf{H}^{(v)} &\approx \frac{1}{2E} \begin{pmatrix} m_1^2 & 0 \\ 0 & m_2^2 \end{pmatrix} + E\mathbf{I} \\ &= \frac{1}{4E} \begin{pmatrix} -\delta m^2 & 0 \\ 0 & \delta m^2 \end{pmatrix} + \left(\frac{m_2^2 + m_1^2}{4E} + E \right) \mathbf{I}. \end{aligned} \quad (2.7)$$

Because a multiple of the identity matrix \mathbf{I} gives only a global phase to the neutrino flavor wave function, I will neglect it from now on, and the vacuum Hamiltonian simplifies to

$$\mathbf{H}^{(v)} \rightarrow \frac{\delta m^2}{4E} \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} = -\frac{\delta m^2}{4E} \sigma_3 = -\frac{\omega_v}{2} \sigma_3, \quad (2.8)$$

where

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \quad (2.9)$$

are the three Pauli matrices. The Schrödinger equation has the following simple

Chapter 2. General Principles of Neutrino Oscillations

solution in the mass basis:

$$\Psi^{(\nu)}(t) = \begin{pmatrix} c_1(0)e^{i\omega_\nu t/2} \\ c_2(0)e^{-i\omega_\nu t/2} \end{pmatrix}. \quad (2.10)$$

Using Eqn. (2.4), I obtain the wave function in the flavor basis,

$$\Psi^{(f)}(t) = \mathbf{U}\Psi^{(\nu)}(t) \quad (2.11)$$

$$= \begin{pmatrix} \cos \theta_\nu & \sin \theta_\nu \\ -\sin \theta_\nu & \cos \theta_\nu \end{pmatrix} \begin{pmatrix} c_1(0)e^{i\omega_\nu t/2} \\ c_2(0)e^{-i\omega_\nu t/2} \end{pmatrix}. \quad (2.12)$$

Alternatively, I can also determine the Hamiltonian in the flavor basis first, which is

$$\mathbf{H}^{(f)} = \mathbf{U}\mathbf{H}^{(\nu)}\mathbf{U}^\dagger = -\frac{\omega_\nu}{2} \cos 2\theta_\nu \sigma_3 + \frac{\omega_\nu}{2} \sin 2\theta_\nu \sigma_1. \quad (2.13)$$

By solving the Schrödinger equation in the flavor basis, I will obtain the same wave function as in Eqn. (2.12).

The probability for a neutrino emitted in the electron flavor at time $t = 0$ to be detected as the electron flavor at a later time t is

$$P(t) = 1 - \sin^2(2\theta_\nu) \sin^2\left(\frac{\omega_\nu t}{2}\right). \quad (2.14)$$

Since the neutrino travels with approximately the speed of light, the electron neutrino survival probability at a distance r from the source is

$$P(r) = 1 - \sin^2(2\theta_\nu) \sin^2\left(\frac{\omega_\nu r}{2}\right). \quad (2.15)$$

I plot the above result in Fig. 2.1 which clearly shows the oscillatory behavior. The oscillation length is determined by the characteristic energy scale ω_ν , which confirms

Chapter 2. General Principles of Neutrino Oscillations

our estimation in Eqn. (2.2). The oscillation amplitude is determined by $\sin^2(2\theta_v)$.

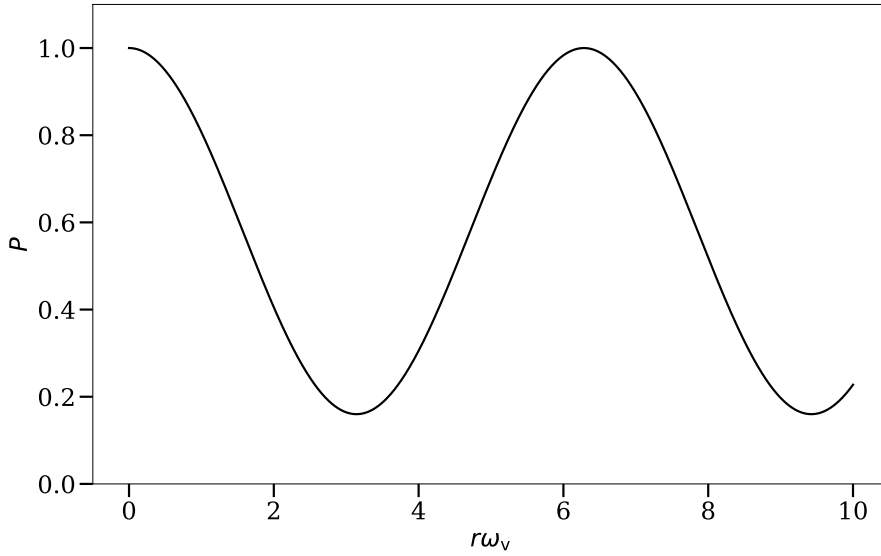

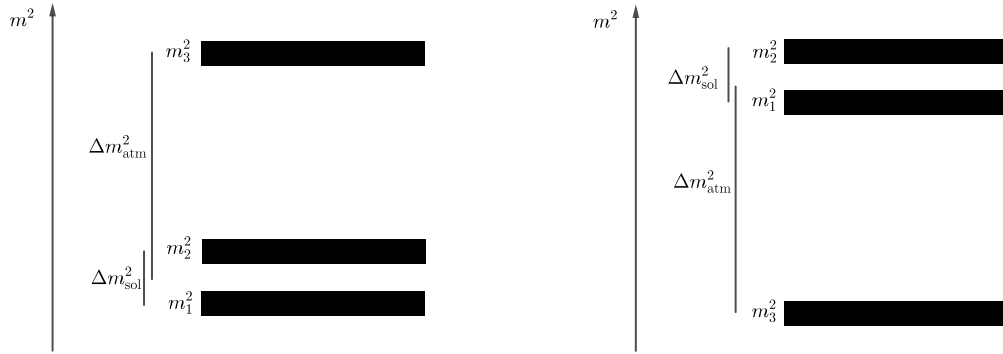

Figure 2.1: The electron flavor neutrino survival probability in vacuum oscillations as a function of distance r which is measured in terms of vacuum oscillation frequency ω_v . The mixing angle θ_v is given by $\sin^2 \theta_v = 0.30 \approx \sin^2 \theta_{12}$.

(a) Normal hierarchy: the third mass is larger than the first two.

(b) Inverted hierarchy: the third mass is smaller than the first two.

Figure 2.2: The order of the three neutrino masses. The difference between the first two masses is responsible for solar neutrino oscillations, and the difference between the third mass and the first two is responsible for atmospheric neutrino oscillations.

In nature, there are three neutrino flavors and, correspondingly, three neutrino

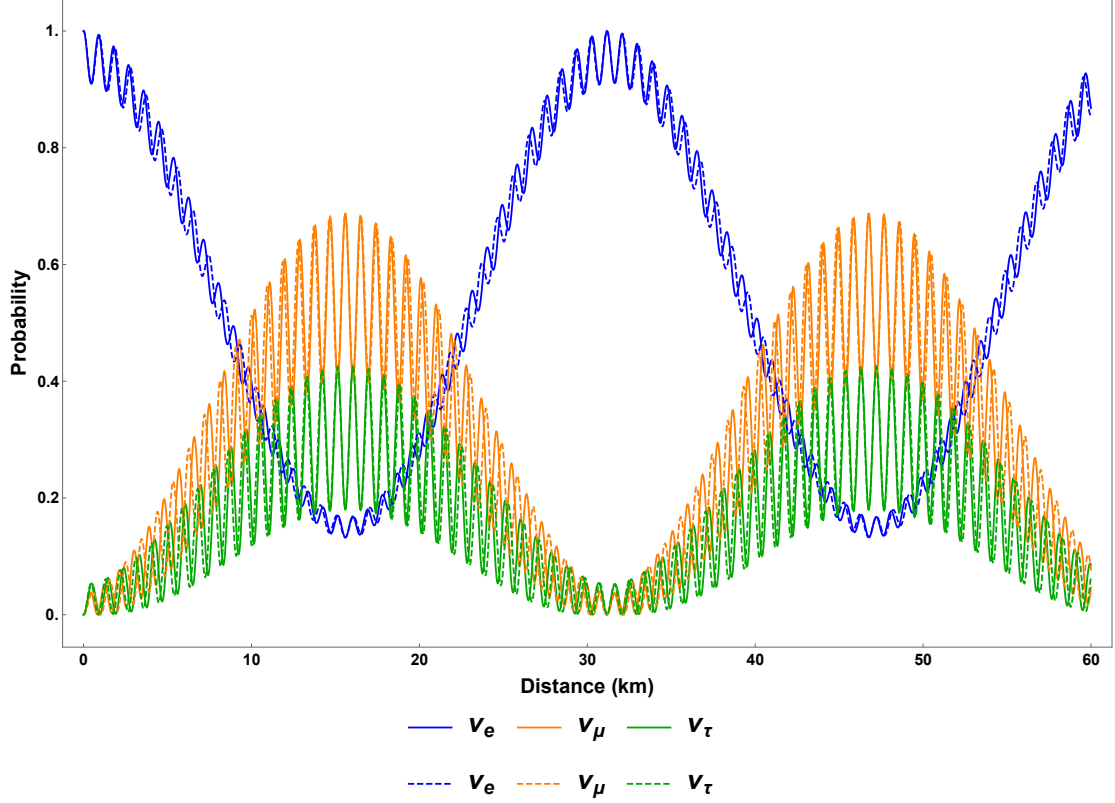

Figure 2.3: The probabilities for a 1MeV neutrino, which is in the electron flavor initially, in different flavors as functions of the distance in vacuum. The solid lines represent the normal hierarchy and the dashed lines represent the inverted hierarchy. The mixing angles are $\sin^2 \theta_{12} = 0.30$, $\sin^2 \theta_{13} = 0.023$, and $\sin^2 \theta_{23} = 0.41$, respectively, and the mass differences are $\delta m_{21}^2 = 7.9 \times 10^{-5} \text{eV}^2$ and $\delta m_{23}^2 = 2.7 \times 10^{-3} \text{eV}^2$.

mass eigenstates as shown in Fig. 2.2. Because there are two different characteristic energy scales, $\omega_{\nu,21} = \delta m_{21}^2/2E$ and $\omega_{\nu,32} = \delta m_{31}^2/2E$, two oscillation periods should occur, as shown in Fig. 2.3. The fast oscillations are determined by the larger energy scale, $\omega_{\nu,32}$, while the slow oscillations are determined by the smaller one $\omega_{\nu,21}$. For the inverted neutrino mass hierarchy (with $m_3 < m_1 < m_2$), the oscillation frequencies are the same as in the normal mass hierarchy (with $m_3 > m_2 > m_1$) since they have the same characteristic energy scales. However, they will develop different phases during oscillations.

2.2 Neutrino Oscillations in Matter

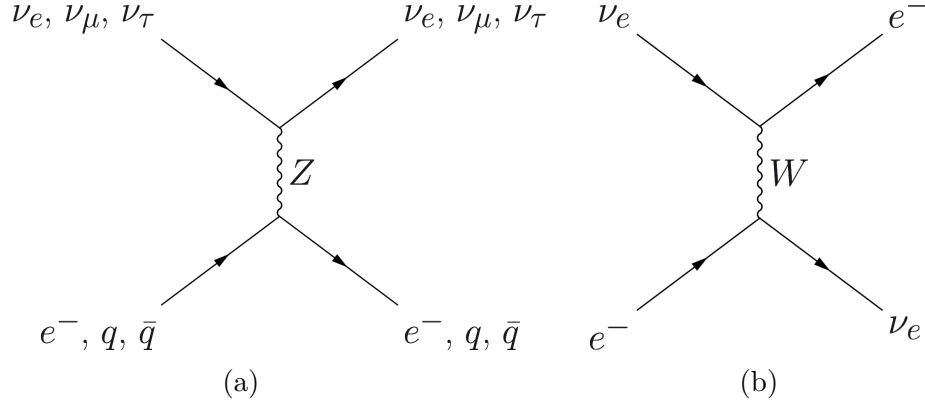

Figure 2.4: (a) The neutral current weak interaction does not distinguish between neutrino flavors and has no impact on neutrino oscillations. (b) The electron flavor neutrino acquires a unique refractive index contribution from the charged current weak interaction with ambient electrons.

In many astrophysical environments such as stars and core-collapse supernovae, neutrinos are mostly produced at the center of the environments and propagate through the dense matter envelope. Although this matter envelope is essentially transparent to neutrinos, the refractive indices of the neutrinos in matter are different than those in vacuum.² Because the neutral current weak interaction does not distinguish between neutrino flavors (see Fig. 2.4a), it has no impact on neutrino oscillations, and I will ignore it from now on. Meanwhile, the electrons and positrons in matter will cause electron flavor neutrinos to have refractive indices different than the neutrinos of other flavors through the charged current weak interaction (see Fig. 2.4b). This leads to an effective potential

$$V^{(f)} = \frac{\sqrt{2}G_F n_e}{2} \sigma_3, \quad (2.16)$$

²The word “matter” in this dissertation refers to ordinary matter composed of electrons, positrons, nucleons and nuclei. I assume that the temperature and density of the environment are not high enough to produce muons and tau particles. I will discuss the effect of the dense neutrino medium in Chapter 4.

Chapter 2. General Principles of Neutrino Oscillations

where $G_F = 1.17 \times 10^{-5} \text{GeV}^{-2}$ is Fermi constant and n_e is net number density of the electron. As usual, I have ignored the trace terms in the above expression.

The Hamiltonian with the matter effect is the combination of Eqn. (2.13) and Eqn. (2.16):

$$\mathbf{H}^{(f)} = \left(\frac{\lambda}{2} - \frac{\omega_v}{2} \cos 2\theta_v \right) \sigma_3 + \frac{\omega_v}{2} \sin 2\theta_v \sigma_1, \quad (2.17)$$

where

$$\lambda = \sqrt{2} G_F n_e. \quad (2.18)$$

Due to the off-diagonal terms in $\mathbf{H}^{(f)}$, the neutrino will experience oscillations in flavor. A resonance with the maximum flavor mixing occurs when the diagonal terms of $\mathbf{H}^{(f)}$ vanish, i.e.,

$$\frac{\lambda}{2} - \frac{\omega_v}{2} \cos 2\theta_v = 0, \quad (2.19)$$

which gives the Mikheyev–Smirnov–Wolfenstein (MSW) resonance condition.

2.3 Neutrino Oscillations in the Sun

The neutrinos produced in the solar core experience decreasing matter density as they travel outward through the Sun. The neutrino propagation eigenstates are different from the flavor states in general [13]. Because the density change inside the Sun is not dramatic, the flavor quantum states of the neutrinos will evolve adiabatically inside the Sun.

The values of the instantaneous eigenstates of the Hamiltonian, known as the

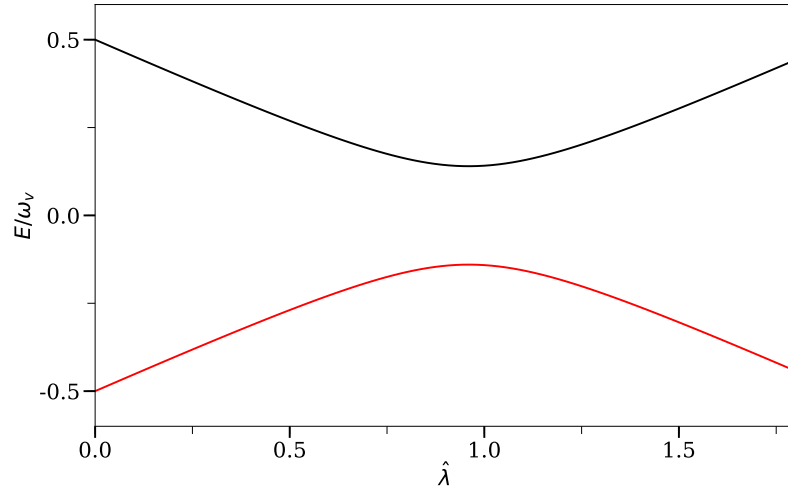

Figure 2.5: The two eigenvalues of the neutrino Hamiltonian as functions of matter potential $\hat{\lambda}$. I have used $\sin^2 \theta_v = 0.02 \approx \sin^2 \theta_{13}$.

“Heavy” and “Light” states, are

$$\varepsilon_H = \frac{\omega_v}{2} \sqrt{\hat{\lambda} + 1 - 2\hat{\lambda} \cos 2\theta_v}, \quad (2.20)$$

$$\varepsilon_L = -\frac{\omega_v}{2} \sqrt{\hat{\lambda} + 1 - 2\hat{\lambda} \cos 2\theta_v}, \quad (2.21)$$

where

$$\hat{\lambda} = \frac{\lambda}{\omega_v}. \quad (2.22)$$

In Fig. 2.5, I show the two eigenvalues of the neutrino Hamiltonian as functions of the matter potential $\hat{\lambda}$.

For a very high matter density, the heavy state of the neutrino $|\nu_H\rangle$ is almost the same as $|\nu_e\rangle$. As the matter density decreases, $|\nu_H\rangle$ becomes a mixture of different neutrino flavors. As the neutrino reaches the surface of the Sun, where the matter density is approximately zero, $|\nu_H\rangle$ is about the same as vacuum mass eigenstate $|\nu_2\rangle$. As a result, the electron flavor neutrinos produced at the solar core are partially converted to other flavors as they reach the surface of the Sun. This explains the

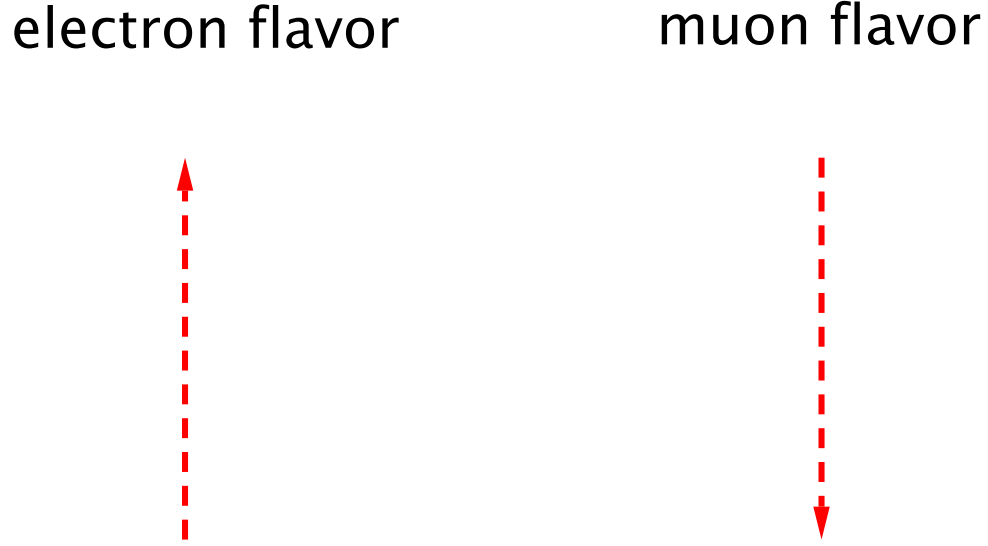

Figure 2.6: In the flavor isospin picture, a flavor isospin pointing upward, i.e., along the third axis in flavor space, indicates that the neutrino is in the electron flavor, while the downward direction indicates the other flavor, such as the muon flavor.

solar neutrino problem.

2.4 Flavor Isospin Formalism

The Hamiltonian for two-flavor neutrino oscillations describes a two-level quantum system. It is known that two-level quantum systems can be visualized using the Bloch sphere. In the realm of neutrino physics, the neutrino flavor isospin was introduced for such purpose [14].

Every two-by-two Hermitian matrix can be expanded in the quaternion basis. For example, the Hamiltonian for neutrino oscillations in vacuum (in the flavor basis) can be written as

$$H^{(f)} = -\frac{\vec{\sigma}}{2} \cdot \vec{H}, \quad (2.23)$$

where

$$\vec{H} = \omega_v \begin{pmatrix} \sin \theta_v \\ 0 \\ \cos 2\theta_v \end{pmatrix}, \quad (2.24)$$

which is a vector of length ω_v and tilted away from the third axis by angle $2\theta_v$. Throughout the dissertation, I will use “ $\vec{}$ ” to denote a vector in flavor space. The flavor quantum state of the neutrino is represented by its flavor isospin which is defined as

$$\vec{s} = \Psi^{(f)\dagger} \frac{\vec{\sigma}}{2} \Psi^{(f)}. \quad (2.25)$$

As shown in Fig. 2.6, the direction of the flavor isospin in flavor space shows the flavor content of the neutrino. A flavor isospin pointing “upward” in flavor space, i.e., along the direction of the third axis, denotes the electron flavor by definition. Correspondingly, the equation of motion for the flavor isospin describes its precession around the vector \vec{H} ,

$$\dot{\vec{s}} = \vec{s} \times \vec{H}, \quad (2.26)$$

where $\dot{}$ indicates the time derivative. In the flavor isospin formalism, the electron flavor survival probability is

$$P = \frac{1}{2} + s_3, \quad (2.27)$$

where s_3 is the third component of the flavor isospin.

Therefore, the precession of the flavor isospin corresponds to a periodic oscillation between the two neutrino flavors (see Fig. 2.7). The oscillation frequency can be trivially read out from Eqn. (2.26):

$$\omega_v = |\vec{H}|. \quad (2.28)$$

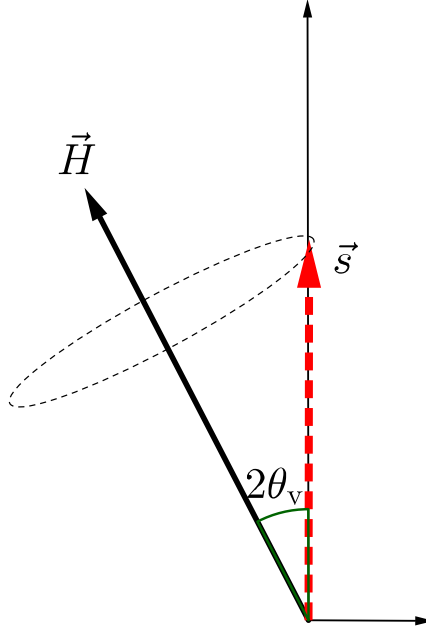

Figure 2.7: Vacuum oscillations in the flavor isospin picture. The flavor isospin of a neutrino starting with the electron flavor precesses around the static “Hamiltonian vector” \vec{H} , which gives a periodic flavor oscillation according to Eqn. (2.15).

The MSW effect can also be easily explained using the flavor isospin picture. The Hamiltonian for the neutrino flavor evolution in the presence of dense matter is

$$H^{(f)} = \frac{\omega_v}{2} (-\cos 2\theta_v \sigma_3 + \sin 2\theta_v \sigma_1) + \frac{\lambda(x)}{2} \sigma_3 \quad (2.29)$$

$$\Rightarrow \vec{H} = \vec{H}_v + \vec{H}_m(x) = \omega_v \begin{pmatrix} -\sin 2\theta_v \\ 0 \\ \cos 2\theta_v \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ -\lambda(x) \end{pmatrix}, \quad (2.30)$$

where \vec{H}_v is the vacuum Hamiltonian, and $\vec{H}_m(x)$ is the matter potential. The precession motion of the flavor isospin of the neutrino in the presence of dense matter is visualized in Fig. 2.8. The MSW resonance condition in Eqn. (2.19) corresponds to the scenario that the overall “Hamiltonian vector” \vec{H} is perpendicular to the third

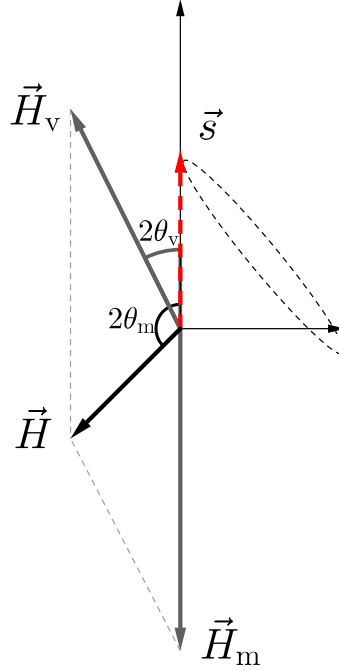

Figure 2.8: Neutrino oscillations in flavor isospin picture with the presence of matter potential. The flavor isospin is denoted as red-dashed arrow. The two gray vectors stand for the vacuum Hamiltonians \vec{H}_v and matter potential \vec{H}_m .

axis in flavor space. In this case, the flavor isospin rotates in the plane spanned by the second and third axes which gives maximum flavor oscillations (see Fig. 2.9).

The adiabatic flavor evolution of the neutrino in a varying matter density profile discussed in Sec. 2.3 can also be easily understood in the flavor-isospin picture. In the region where the matter density is high, the total “Hamiltonian vector” \vec{H} points “downward” in flavor space. Therefore, a neutrino produced in the electron flavor will experience very little oscillation because its flavor isospin \vec{s} is almost anti-parallel to \vec{H} (see Fig. 2.10a). If the matter density along the propagation trajectory of the neutrino decreases slowly, \vec{s} will stay almost anti-parallel to \vec{H} as \vec{H} rotates (see Fig. 2.10b). When the neutrino reaches the region with very low matter density, its flavor isospin becomes almost anti-parallel to \vec{H}_v , which implies that the neutrino is in $|\nu_2\rangle$ (see Fig. 2.10).

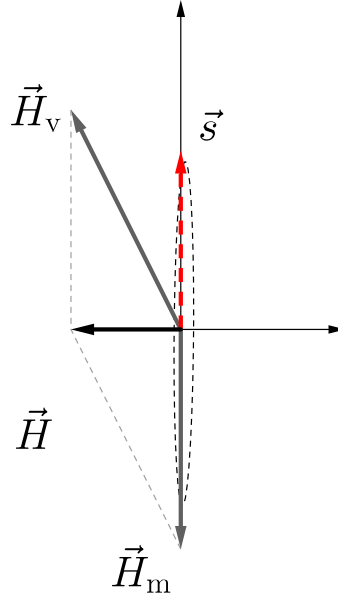

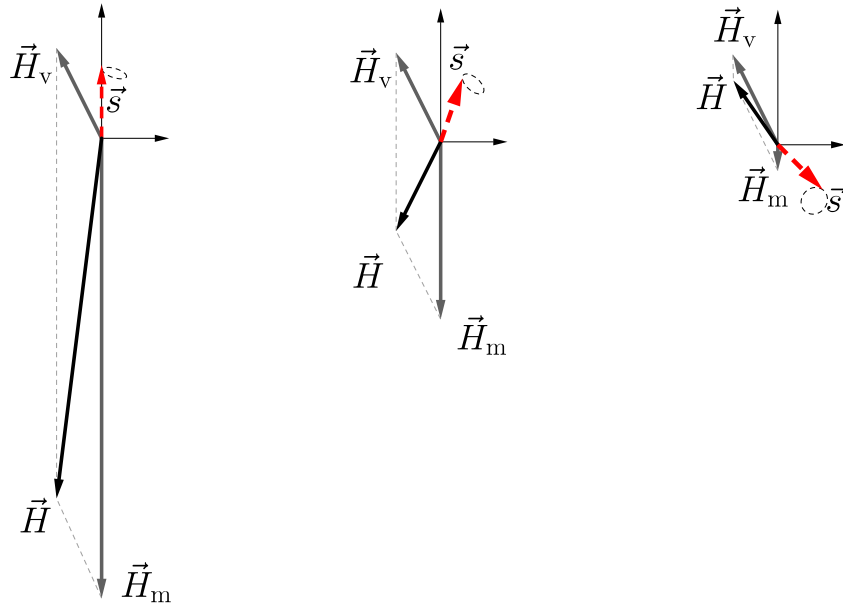

Figure 2.9: MSW resonance occurs when Eqn. (2.19) is satisfied.

2.5 Summary

Neutrino oscillations in vacuum and in matter with a smooth profile have been explained. The neutrino oscillation phenomenon reveals a secret of the nature of the neutrino, i.e., its flavor states are not the same as the mass eigenstates of the Hamiltonian. As a result, a neutrino produced in the pure flavor state through weak interaction will not remain in the same flavor state as it propagates, but oscillates between different flavors. The problem of neutrino oscillations in an environment with rapidly varying matter densities is significantly more difficult than that in a smooth profile. This will be discussed in the next chapter.

(a) High matter density (b) Medium matter density (c) Low matter density

Figure 2.10: Flavor isospin picture of neutrino oscillations in matter. \vec{H}_v is the vacuum Hamiltonian, and \vec{H}_m is the matter potential.

Chapter 3

Neutrino Oscillations with Oscillatory Matter Profiles

In certain regions inside a star or a supernova where convection is prominent, the matter density varies rapidly as a function of distance [15, 16]. The neutrino flavor evolution in such environments is qualitatively different than that with a smooth density profile [17–23]. For example, the flavor conversion of the neutrino is greatly enhanced if the matter density fluctuates with certain wavenumbers. This is known as the parametric resonance [17, 24].

In this chapter, I will explain the parametric resonance from the perspective of Rabi oscillations. I will first review the Rabi oscillation phenomenon and derive a criterion when the off-resonance Rabi mode may have a significant impact on the resonance behavior. I will then introduce the background matter basis with which the equation of motion simplifies. After demonstrating the simplest example of the parametric resonance in the presence of a sinusoidal matter profile with the Rabi formula, I will explain the interference effect when there exist multiple Fourier modes in the matter profile. Finally I will show how to use the Jacobi-Anger expansion to decompose an arbitrary matter profile into an infinite sum of Rabi modes. This decomposition is similar to what J. Kneller et al. did in reference [22, 23] but is achieved in a way that makes the physics much more transparent. I will also use the criterion that I have derived for the interference between two Rabi modes to show that only a finite number of Rabi modes are relevant in a real physical system.

3.1 Rabi Oscillations

Figure 3.1: A two-level quantum system that experiences the Rabi oscillations. The resonance occurs when the frequency of the driving field ω equals the energy gap $\omega_R = \varepsilon_2 - \varepsilon_1$.

A two-level quantum system with energy gap $\delta\varepsilon = \omega_R$ can experience Rabi oscillations when some light with frequency ω shines on it (see Fig. 3.1). The Hamiltonian for the system is

$$\mathbf{H}_R = -\frac{\omega_R}{2}\sigma_3 - \frac{A_R}{2}(\cos(k_R t)\sigma_1 - \sin(k_R t)\sigma_2), \quad (3.1)$$

where A_R and k_R are the amplitude and frequency of the driving field, respectively. The Hamiltonian \mathbf{H}_R can be mapped on to a vector using the flavor isospin picture:

$$\vec{H}_R = \vec{H}_3 + \vec{H}_+, \quad (3.2)$$

where

$$\vec{H}_3 = \begin{pmatrix} 0 \\ 0 \\ \omega_R \end{pmatrix} \quad \text{and} \quad \vec{H}_+ = \begin{pmatrix} A_R \cos(k_R t) \\ -A_R \sin(k_R t) \\ 0 \end{pmatrix}. \quad (3.3)$$

The vector \vec{H}_3 is the vector aligned with the third axis and \vec{H}_+ is a vector rotating in a plane perpendicular to \vec{H}_3 (see Fig. 3.2a). The wave function $\Psi = (\psi_1, \psi_2)^T$ is

also used to define the state vector \vec{s}

$$\vec{s} = \Psi^\dagger \frac{\vec{\sigma}}{2} \Psi = \frac{1}{2} \begin{pmatrix} 2 \operatorname{Re}(\psi_1^* \psi_2) \\ 2 \operatorname{Im}(\psi_1^* \psi_2) \\ |\psi_1|^2 - |\psi_2|^2 \end{pmatrix}. \quad (3.4)$$

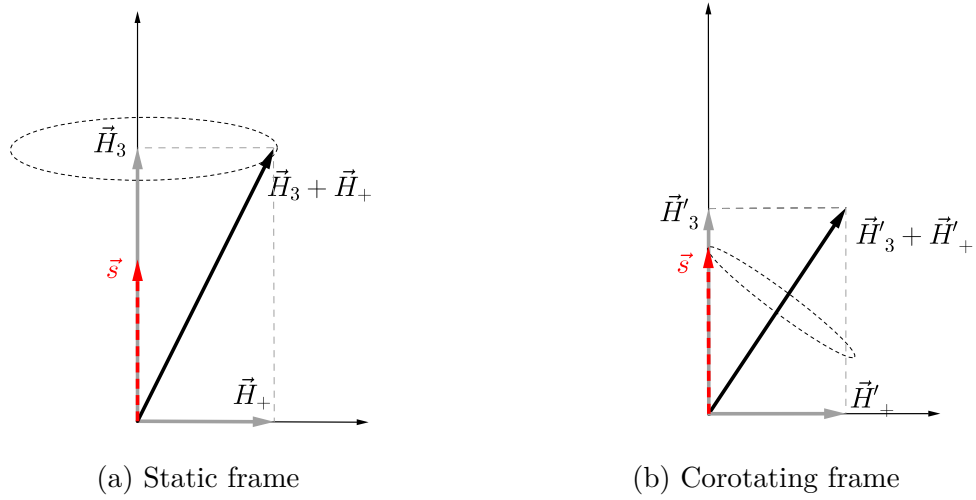

Figure 3.2: Rabi oscillations in different frames. The vectors \vec{H}_3 and \vec{H}_+ are defined in Eqn. (3.3). The red dashed vector \vec{s} represents the quantum state of the system, and the black solid vectors are for the Hamiltonians in the corresponding frames.

The third component of \vec{s} , which is denoted as s_3 , is within the range $[-1/2, 1/2]$. The two limits, $s_3 = -1/2$ and $s_3 = 1/2$ stand for the high energy state and the low energy state of the two-level system, respectively. If the two-level system has equal probabilities to be in the high energy state and the low energy state, one has $s_3 = 0$. The equation of motion of \vec{s} is the same as Eqn. (2.26) and describes the precession of \vec{s} .

In this example, the total “Hamiltonian vector” \vec{H}_R is not static since it has a rotating component \vec{H}_+ . A more convenient frame is the one that corotates with \vec{H}_+ ,

which is depicted in Fig. 3.2b. The equation of motion of \vec{s} in this frame is

$$\frac{d}{dt}\vec{s} = \vec{s} \times (\vec{H}'_3 + \vec{H}_+), \quad (3.5)$$

where

$$\vec{H}'_3 = \begin{pmatrix} 0 \\ 0 \\ \omega_R - k_R \end{pmatrix} \quad \text{and} \quad \vec{H}_+ = \begin{pmatrix} A_R \\ 0 \\ 0 \end{pmatrix}. \quad (3.6)$$

The state vector \vec{s} precesses around the static vector $\vec{H}'_3 + \vec{H}_+$ in this corotating frame with a frequency

$$\Omega_R = \sqrt{|A_R|^2 + (k_R - \omega_R)^2} \quad (3.7)$$

which is known as the Rabi frequency. Projecting the state vector \vec{s} on to the third axis, I obtain

$$s_3 = \frac{1}{2} - \frac{|A_R|^2}{\Omega_R^2} \sin^2 \left(\frac{\Omega_R}{2} t \right). \quad (3.8)$$

Such a system has a transition probability from the low energy state to the high energy state, given by the Rabi formula,

$$P(t) = \frac{1}{2} [1 - 2s_3(t)] = \frac{1}{1 + D^2} \sin^2 \left(\frac{\Omega_R}{2} t \right), \quad (3.9)$$

where

$$D = \left| \frac{k_R - \omega_R}{A_R} \right|. \quad (3.10)$$

is the relative detuning.

The resonance of Rabi oscillations occurs when $\vec{H}'_3 = 0$ in the corotating frame and s_3 oscillates between $+1/2$ (the low energy state) and $-1/2$ (the high energy state). The transition amplitude is determined by the relative detuning D as illustrated by the two numerical examples in Fig. 3.3. The resonance width is determined by the

amplitude of the driving field A_R as shown in Fig. 3.4.

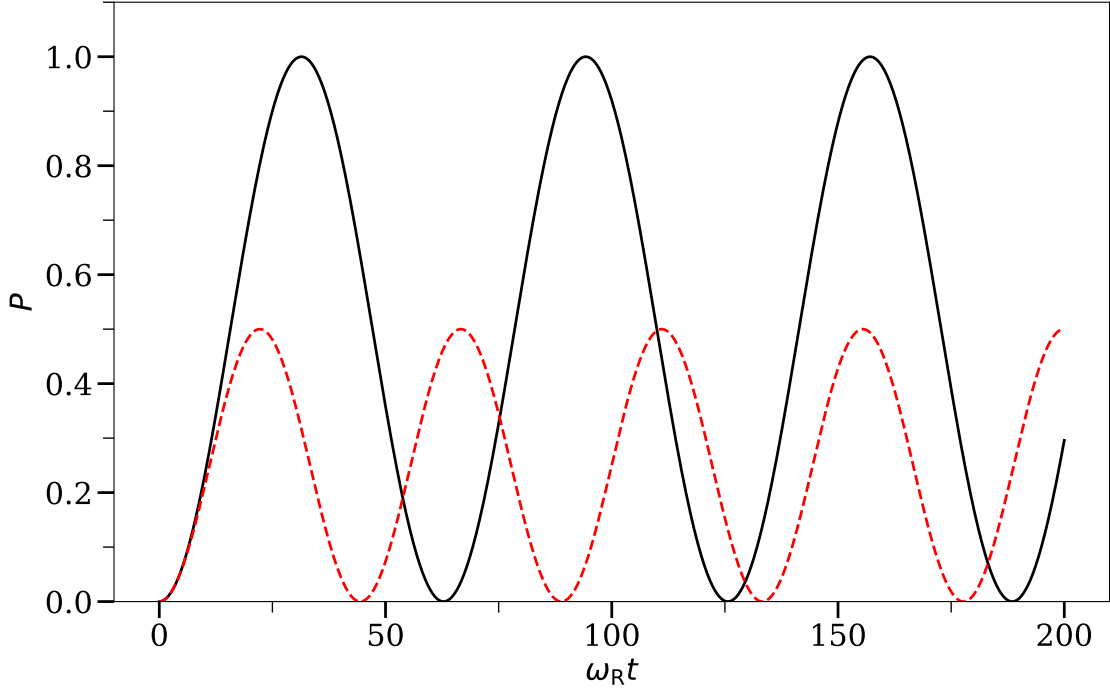

Figure 3.3: The transition probabilities P between the energy states of a two-level quantum system when external driving fields with frequencies $k_R = \omega_R$ and $k_R = 1.1\omega_R$ are applied, respectively. The corresponding relative detunings are $D = 0$ and $D = 1$, respectively. The amplitudes of the driving fields are $A_R = 0.1\omega_R$ in both cases.

In many cases, the two-level quantum system has more than one driving field. I will refer to each of the driving fields as a Rabi mode. Here I consider the Hamiltonian with two Rabi modes:

$$\begin{aligned} H_R = & -\frac{\omega_R}{2}\sigma_3 - \frac{A_1}{2}(\cos(k_1 t)\sigma_1 - \sin(k_1 t)\sigma_2) \\ & - \frac{A_2}{2}(\cos(k_2 t)\sigma_1 - \sin(k_2 t)\sigma_2). \end{aligned} \quad (3.11)$$

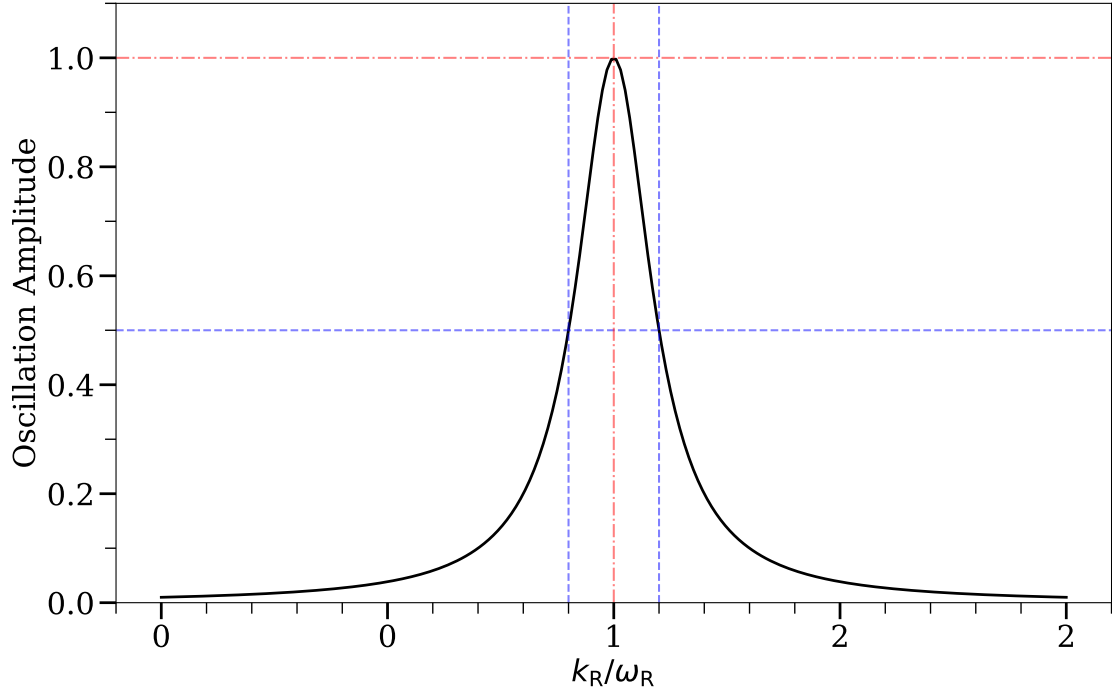

Figure 3.4: The amplitude of Rabi oscillations as a function of the frequency of the external driving field k_R . The maximum amplitude occurs at $k_R/\omega_R = 1$. The resonance width is defined to be the difference of k_R at which the amplitudes are $1/2$.

I decompose it into $\vec{H}_R = \vec{H}_3 + \vec{H}_1 + \vec{H}_2$, where

$$\vec{H}_1 = \begin{pmatrix} A_1 \cos(k_1 t) \\ -A_1 \sin(k_1 t) \\ 0 \end{pmatrix} \quad \text{and} \quad \vec{H}_2 = \begin{pmatrix} A_2 \cos(k_2 t) \\ -A_2 \sin(k_2 t) \\ 0 \end{pmatrix}.$$

I will assume that the first Rabi mode \vec{H}_1 is almost on resonance, and the second one \vec{H}_2 is off resonance, i.e.,

$$D_1 \lesssim 1 \quad \text{and} \quad D_2 \gg 1, \quad (3.12)$$

where

$$D_i \equiv \frac{|k_i - \omega_R|}{|A_i|} \quad (3.13)$$

is the relative detuning of the i th Rabi mode.

Chapter 3. Neutrino Oscillations with Oscillatory Matter Profiles

Although the second Rabi mode is off resonance, it can interfere with the Rabi oscillation caused by the first Rabi mode. To see this effect, I will use the frame that corotates with \vec{H}_2 . In the corotating frame, the two Rabi modes have frequencies $k'_1 = k_1 - k_2$ and $k'_2 = 0$, respectively, and $\vec{H}'_3 = (0, 0, \omega_R - k_2)^T$. Obviously, the Hamiltonian vector in this corotating frame is similar to Eqn. (3.2) except with the replacements

$$\vec{H}_3 \rightarrow \vec{H}'_3 + \vec{H}'_2 \quad \text{and} \quad \vec{H}_+ \rightarrow \vec{H}'_1. \quad (3.14)$$

I will further assume that $|A_2| \ll \omega_R$ so that the new energy gap is

$$\begin{aligned} \tilde{\omega}'_R &\equiv |\vec{H}'_3 + \vec{H}'_2| \text{Sign}(\omega_R - k_2) \\ &= \text{Sign}(\omega_R - k_2) \sqrt{(\omega_R - k_2)^2 + A_2^2} \\ &\approx \omega_R - k_2 + \frac{1}{2} \frac{A_2^2}{\omega_R - k_2}, \end{aligned} \quad (3.15)$$

where I have kept only up to the first order of the Taylor series. I can calculate the new relative detuning of the system to be

$$\begin{aligned} D' &= \frac{|k'_1 - \tilde{\omega}'_R|}{|A_1|} \\ &\approx \left| \frac{k_1 - \omega_R}{A_1} + \frac{A_2^2}{2A_1(k_2 - \omega_R)} \right|. \end{aligned} \quad (3.16)$$

One can adjust the frequency of the off-resonance Rabi mode k_2 to decrease or increase D so that the system is closer to or further away from the resonance. The criterion for the off-resonance Rabi mode to have a significant impact on the Rabi resonance is

$$\left| \frac{A_2^2}{2A_1(k_2 - \omega_R)} \right| \gtrsim 1 \quad \text{or} \quad |A_2| \gtrsim \sqrt{2|A_1(k_2 - \omega_R)|} \quad (3.17)$$

3.2 Background Matter Basis

For a uniform matter density $\lambda(r) = \lambda_0$, one can define a matter basis in which the Hamiltonian is diagonalized:

$$\mathbf{H}^{(\text{m})} = \mathbf{U}^\dagger \mathbf{H}^{(\text{f})} \mathbf{U} = -\frac{\omega_{\text{m}}}{2} \sigma_3, \quad (3.18)$$

where

$$\mathbf{U} = \begin{pmatrix} \cos \theta_{\text{m}} & \sin \theta_{\text{m}} \\ \sin \theta_{\text{m}} & \cos \theta_{\text{m}} \end{pmatrix} \quad (3.19)$$

with

$$\theta_{\text{m}} = \frac{1}{2} \arctan \left(\frac{\sin 2\theta_{\text{v}}}{\cos 2\theta_{\text{v}} - \lambda_0/\omega_{\text{v}}} \right), \quad (3.20)$$

and

$$\omega_{\text{m}} = \omega_{\text{v}} \sqrt{(\lambda_0/\omega_{\text{v}} - \cos(2\theta_{\text{v}}))^2 + \sin^2(2\theta_{\text{v}})} \quad (3.21)$$

is the neutrino oscillation frequency in matter.

In the rest of the chapter, I will consider the matter profiles of the form

$$\lambda(r) = \lambda_0 + \delta\lambda(r), \quad (3.22)$$

where $\delta\lambda(r)$ describes the fluctuation of the matter density. I will use the background matter basis defined in Eqn. 3.18, Eqn. (3.20) and Eqn. (3.21). In this basis, the Hamiltonian reads

$$\mathbf{H}^{(\text{m})} = -\frac{\omega_{\text{m}}}{2} \sigma_3 + \frac{1}{2} \delta\lambda(r) \cos 2\theta_{\text{m}} \sigma_3 - \frac{1}{2} \delta\lambda(r) \sin 2\theta_{\text{m}} \sigma_1. \quad (3.23)$$

In this chapter, I will focus on the transition probability between the background

matter eigenstates

$$\begin{pmatrix} |\nu_L\rangle \\ |\nu_H\rangle \end{pmatrix} = U^\dagger \begin{pmatrix} |\nu_e\rangle \\ |\nu_x\rangle \end{pmatrix}. \quad (3.24)$$

Given this transition probability, it is trivial to calculate the conversion between flavors.

All the numerical examples in this chapter are calculated with $\sin^2(2\theta_v) = 0.093$ and $\omega_v = 3.75 \times 10^{-17} \text{MeV}$ [2].

3.3 Single-Frequency Matter Profiles

I will examine the neutrino flavor conversion in a single-frequency matter profile $\delta\lambda(r) = \lambda_1 \cos(k_1 r)$. I will assume that the perturbation is small so that $\lambda_1 \ll \omega_m$. The Hamiltonian in the background matter basis becomes

$$H^{(m)} = -\frac{\omega_m}{2}\sigma_3 + \frac{1}{2}\lambda_1 \cos(k_1 r) \cos 2\theta_m \sigma_3 - \frac{1}{2}\lambda_1 \cos(k_1 r) \sin 2\theta_m \sigma_1. \quad (3.25)$$

I will consider the case when k_1 is not far away from resonance, i.e., $k_1 \sim \omega_m$. As will be proven later, the oscillating σ_3 term in the above Hamiltonian has little effect on the transition probabilities in this case. With the oscillating σ_3 term removed,

$$\begin{aligned} H^{(m)} \rightarrow & -\frac{\omega_m}{2}\sigma_3 - \frac{1}{2}A_1 \cos(k_1 r)\sigma_1 + \frac{1}{2}A_1 \sin(k_1 r)\sigma_2 \\ & - \frac{1}{2}A_2 \cos(k_2 r)\sigma_1 + \frac{1}{2}A_2 \sin(k_2 r)\sigma_2 \end{aligned} \quad (3.26)$$

where

$$A_1 = A_2 = \frac{\lambda_1 \sin(2\theta_m)}{2} \quad \text{and} \quad k_2 = -k_1. \quad (3.27)$$

Chapter 3. Neutrino Oscillations with Oscillatory Matter Profiles

This is the same as the Hamiltonian H_R in Eqn. (3.11). Because the second Rabi mode is off resonance and its amplitude is too small to satisfy the criterion in Eqn. (3.17), it can be neglected and Rabi formula in Eqn. (3.9) can be applied with $A_R = A_1$, $k_R = k_1$, and $\omega_R = \omega_m$.

I calculated the transition probability using the Hamiltonian in Eqn. (3.25) with $k_1/\omega_m = 1$ and plotted it as black square markers in Fig. 3.5. For comparison I also plotted the transition probability obtained from the Rabi formula in Eqn. (3.9) as the dot-dashed curve in the same figure, which agrees with the numerical result very well. In this case, the first Rabi mode is exactly on resonance with relative detuning $D_1 = 0$. I calculated the transition probabilities for additional two cases with $k_1/\omega_m = 1 - 2 \times 10^{-5}$ and $1 - 10^{-4}$, which have relative detunings $D_1 = 1$ and 5.2, respectively. The Rabi resonance is suppressed as D_1 increases. The results obtained using the full Hamiltonian and those from the Rabi formula again agree very well.

For a single-frequency perturbation in the matter profile $\lambda(r) = \lambda_0 + \lambda_1 \sin(k_1 r)$, P. Krastev and A. Smirnov concluded that the parametric resonance condition is $\omega_m \sim nk_1$ if

$$\omega_{m,\text{inst}}(r) = \omega_v \sqrt{[\lambda(r)/\omega_v - \cos(2\theta_v)]^2 + \sin^2(2\theta_v)} \quad (3.28)$$

varies slowly with r [17]. This condition is exactly the Rabi resonance condition when $n = 1$. Higher order effects will be explained in Sec. 3.6.

3.4 Multi-Frequency Matter Profiles

The approach applied to the neutrino flavor transformation with a single-frequency matter profile can also be used in more general cases with multi-frequency matter profiles. Even though there is only one Rabi mode that is on resonance, the presence

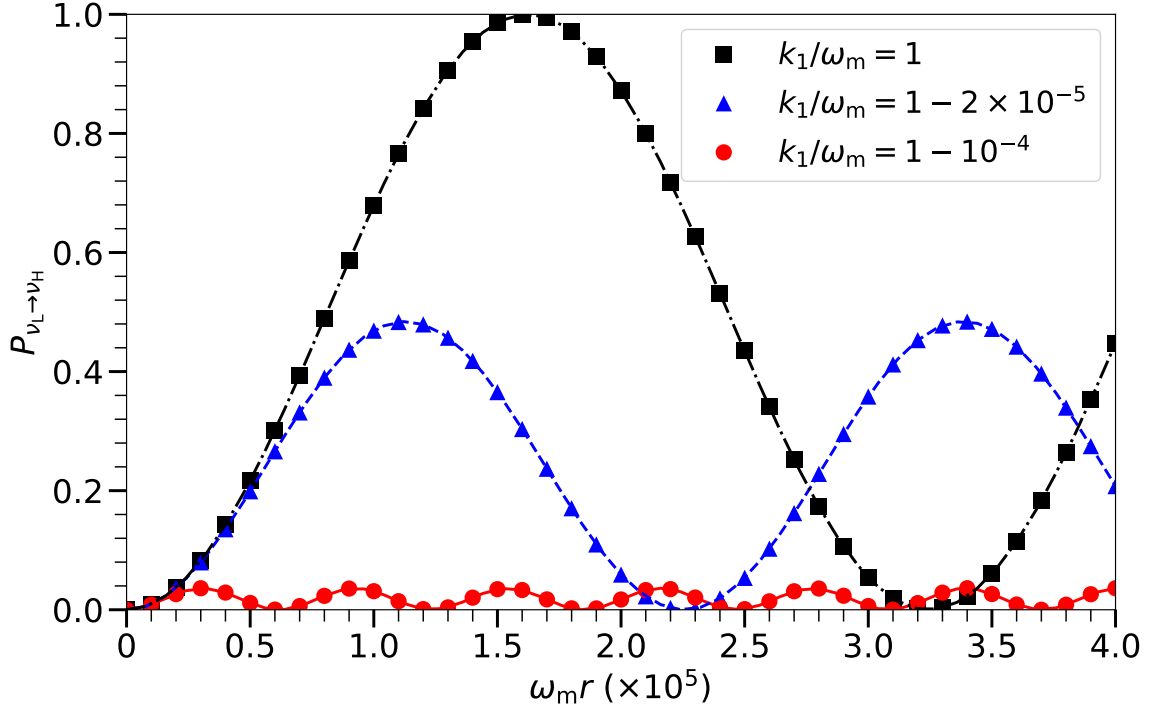

Figure 3.5: The transition probabilities $P_{\nu_L \rightarrow \nu_H}$ as functions of distance r for a neutrino propagating through matter profiles of the form $\lambda(r) = \lambda_0 + \lambda_1 \cos(k_1 r)$ with different values of k_1 as labeled. The markers are for the numerical results obtained by using the Hamiltonian in Eqn. (3.25), and the continuous curves are obtained using the Rabi formula in Eqn. (3.9). In all three cases, λ_0 is half of the MSW resonance potential, and $\lambda_1/\omega_m = 5.2 \times 10^{-4}$.

of many off-resonance Rabi modes may interfere with the on-resonance mode and suppress or enhance the neutrino flavor conversions.

I will consider a matter profile with two Fourier modes:

$$\lambda(r) = \lambda_0 + \lambda_1 \cos(k_1 r) + \lambda_2 \cos(k_2 r). \quad (3.29)$$

The Hamiltonian for the neutrino oscillations in the background matter basis is

$$\begin{aligned} H^{(m)} = & -\frac{\omega_m}{2} \sigma_3 + \frac{1}{2} (\lambda_1 \cos(k_1 r) + \lambda_2 \cos(k_2 r)) \cos 2\theta_m \sigma_3 \\ & - \frac{1}{2} (\lambda_1 \cos(k_1 r) + \lambda_2 \cos(k_2 r)) \sin 2\theta_m \sigma_1. \end{aligned} \quad (3.30)$$

Chapter 3. Neutrino Oscillations with Oscillatory Matter Profiles

I will drop the oscillating σ_3 terms for the same reason as in the single-frequency matter profile case. The Hamiltonian becomes

$$H^{(m)} \rightarrow -\frac{\omega_m}{2}\sigma_3 - \sum_n \frac{A_n}{2} \cos(k_n r) \sigma_1 + \sum_n \frac{A_n}{2} \sin(k_n r) \sigma_2. \quad (3.31)$$

There are four Rabi modes in this Hamiltonian, $n = 1+, 1-, 2+, \text{ and } 2-$. The amplitudes and wavenumbers of the four Rabi modes are

$$A_{1\pm} = \frac{\lambda_1 \sin(2\theta_m)}{2}, \quad k_{1\pm} = \pm k_1, \quad (3.32)$$

$$A_{2\pm} = \frac{\lambda_2 \sin(2\theta_m)}{2}, \quad k_{2\pm} = \pm k_2, \quad (3.33)$$

respectively.

The presence of the additional Fourier mode can suppress the Rabi resonance. This is illustrated in Fig. 3.6. In this figure, I choose the $1+$ Rabi mode to be exactly on resonance with $\lambda_1/\omega_m = 5.2 \times 10^{-4}$ and $k_1/\omega_m = 1$. The triangles represent the numerical solution for neutrino flavor transformation with $\lambda_2/\omega_m = 0.052$ and $k_2/\omega_m = 0.1$. One can see that the transition amplitude is suppressed due to the presence of the second Fourier mode. I used Eqn. (3.16) to calculate the modified relative detunings by taking into account only the $1+$ mode and another Rabi mode. The values of the relative detunings are listed in Table 3.1. I calculated the transition probability using the Rabi formula in Eqn. (3.9) with the relative detuning $D'_{(2+)}$ (the continuous curve in the figure), and it agrees with the numerical solution very well. I also showed two additional examples with $(\lambda_2/\omega_m, k_2/\omega_m)$ being $(0.052, 10)$ and $(0.26, 10)$, respectively. In both examples, the numerical solutions and the analytic results by using the Rabi formula have excellent agreement.

The presence of the second Fourier mode can also enhance the Rabi resonance,

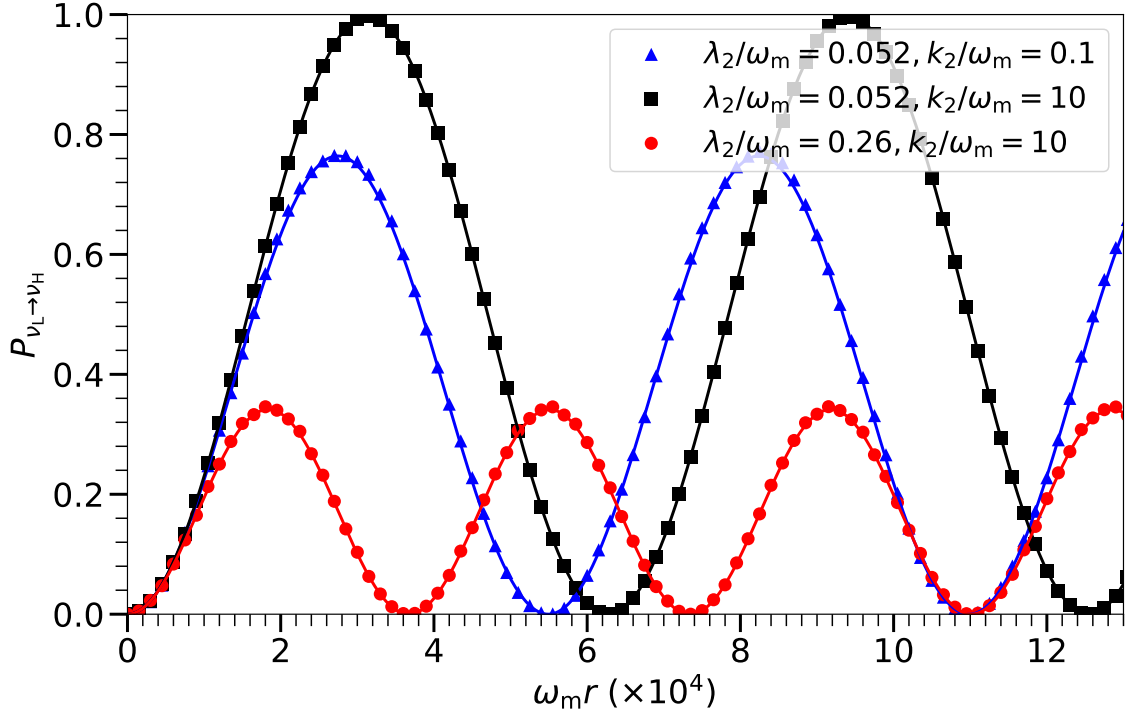

Figure 3.6: The transition probabilities as functions of distance r for a neutrino propagating through matter profile of the form $\lambda(r) = \lambda_0 + \lambda_1 \cos(k_1 r) + \lambda_2 \cos(k_2 r)$ with different values of λ_2 and k_2 as labeled. The markers are for the numerical results obtained by using the Hamiltonian in Eqn. (3.30), and the continuous curves are obtained using the Rabi formula in Eqn. (3.9) but with the values of the modified relative detunings D'_{2+} in Table 3.1. In all three cases, λ_0 is half of the MSW resonance potential, $\lambda_1/\omega_m = 5.2 \times 10^{-4}$ and $k_1/\omega_m = 1$.

which is illustrated in Fig. 3.7. The two Fourier modes in this figure have amplitudes and wavenumbers

$$\begin{aligned} \lambda_1/\omega_m &= 5.2 \times 10^{-4}, & k_1/\omega_m &= 1 - 10^{-4}, \\ \lambda_2/\omega_m &= 0.1, & k_2/\omega_m &= 3, \end{aligned}$$

λ_2/ω_m	k_2/ω_m	$D'_{(1-)}$	$D'_{(2+)}$	$D'_{(2-)}$
0.052	0.1	2.5×10^{-5}	0.56	0.46
0.052	10	2.5×10^{-5}	0.056	0.045
0.26	10	2.5×10^{-5}	1.4	1.1

Table 3.1: The relative detunings of the Rabi resonance when only the 1+ mode and another Rabi mode are considered.

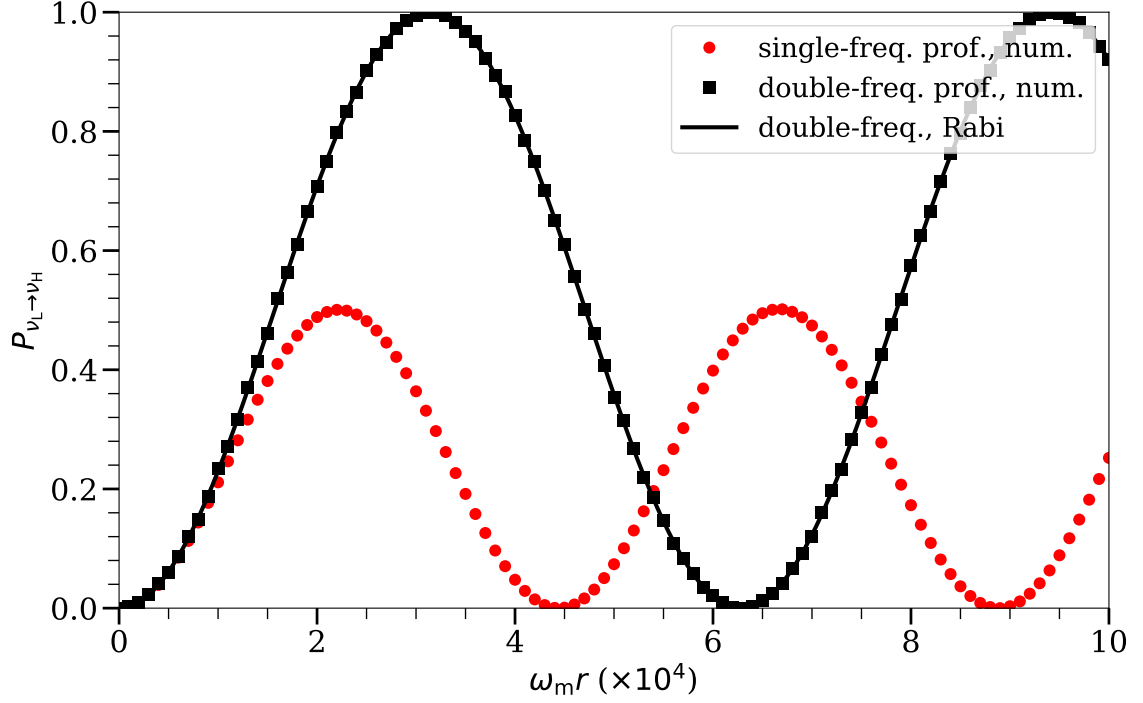

Figure 3.7: The constructive interference effect for the neutrino flavor conversion with a two-frequency matter density profile similar to that in Fig. 3.6. The red dots represent the numerical solution in the case of a single-frequency matter profile with $\lambda_1/\omega_m = 5.2 \times 10^{-4}$ and $k_1/\omega_m = 1 - 10^{-4}$. The black square markers represent the numerical solution with an additional Fourier mode with $\lambda_2/\omega_m = 0.1$ and $k_2/\omega_m = 3$. The black curve is obtained using the Rabi formula in Eqn. (3.9) with relative detuning $D'_{(2+)} = 0$.

respectively. The neutrino flavor conversion is never complete if only the first Fourier mode is present because the relative detuning $D_{1+} = 1 > 0$. This is shown as the red dots in the figure. However, complete neutrino flavor conversion occurs when both Fourier modes are present. This is because the modified relative detuning $D'_{(2+)} = 0$ when only the 1+ and the 2+ Rabi modes are considered. The numerical solution and the analytic prediction using the Rabi formula are plotted as the black squares and the continuous curve, respectively, which agree very well.

3.5 Rabi Basis

Previously I have ignored the oscillating σ_3 terms in the Hamiltonian such as in Eqn. (3.25). Using the Jacobi-Anger expansion, J. Kneller et al. showed that these terms result in an infinite number of resonance conditions. In the rest of the chapter, I will present a much simpler derivation of their results from the perspective of Rabi oscillations. For this purpose I will define a new basis called Rabi basis

$$\begin{pmatrix} |\nu_{r1}\rangle \\ |\nu_{r2}\rangle \end{pmatrix} = U^\dagger \begin{pmatrix} |\nu_L\rangle \\ |\nu_H\rangle \end{pmatrix}, \quad (3.34)$$

where

$$U = \begin{pmatrix} e^{-i\eta(r)} & 0 \\ 0 & e^{i\eta(r)} \end{pmatrix}. \quad (3.35)$$

The unitary transformation in Eqn. (3.35) is a rotation in flavor space about the third axis. It commutes with σ_3 terms in the Hamiltonian, but, due to its dependence on r , the left side of the Schrödinger equation obtains an extra term:

$$\begin{aligned} & \begin{pmatrix} \frac{d\eta}{dr} & 0 \\ 0 & -\frac{d\eta}{dr} \end{pmatrix} \begin{pmatrix} \psi_{R1} \\ \psi_{R2} \end{pmatrix} + i \frac{d}{dr} \begin{pmatrix} \psi_{R1} \\ \psi_{R2} \end{pmatrix} \\ &= \left[-\frac{\omega_m}{2} \sigma_3 + \frac{\delta\lambda}{2} \cos 2\theta_m \sigma_3 - \frac{\delta\lambda}{2} \sin 2\theta_m \begin{pmatrix} 0 & e^{2i\eta} \\ e^{-2i\eta} & 0 \end{pmatrix} \right] \begin{pmatrix} \psi_{R1} \\ \psi_{R2} \end{pmatrix}. \end{aligned}$$

The oscillating σ_3 terms in Hamiltonian can be eliminated by choosing $\eta(r)$ properly, i.e.,

$$\eta(r) - \eta(0) = \frac{\cos 2\theta_m}{2} \int_0^r \delta\lambda(\tau) d\tau. \quad (3.36)$$

With this definition, the Schrödinger equation simplifies:

$$i \frac{d}{dr} \begin{pmatrix} \psi_{r1} \\ \psi_{r2} \end{pmatrix} = \left[-\frac{\omega_m}{2} \sigma_3 - \frac{\delta\lambda}{2} \sin 2\theta_m \begin{pmatrix} 0 & e^{2i\eta} \\ e^{-2i\eta} & 0 \end{pmatrix} \right] \begin{pmatrix} \psi_{r1} \\ \psi_{r2} \end{pmatrix}. \quad (3.37)$$

Because the states $|\nu_{r1}\rangle$ and $|\nu_{r2}\rangle$ are related to $|\nu_L\rangle$ and $|\nu_H\rangle$ by phase factors only, the transition probability between the former two states is the same as that between the latter.

3.6 Single-Frequency Matter Profiles Revisited

Let us consider the single-frequency matter profile that we have studied in Sec. 3.3 again. In the Rabi basis, the Hamiltonian becomes

$$H^{(R)} = \frac{\omega_m}{2} \sigma_3 - \frac{\sin 2\theta_m \lambda_1 \cos(k_1 r)}{2} \begin{pmatrix} 0 & e^{2i\eta(r)} \\ e^{-2i\eta(r)} & 0 \end{pmatrix}, \quad (3.38)$$

where

$$\eta(r) = \frac{\lambda_1 \cos 2\theta_m}{2k} \sin(k_1 r). \quad (3.39)$$

With the Jacobi-Anger expansion

$$e^{iz \sin(\phi)} = \sum_{n=-\infty}^{\infty} J_n(z) e^{in\phi}, \quad (3.40)$$

the term $e^{2i\eta(r)}$ becomes

$$\exp\left(i \frac{\lambda_1 \cos 2\theta_m}{k_1} \sin(k_1 r)\right) = \sum_{n=-\infty}^{\infty} J_n\left(\frac{\lambda_1 \cos 2\theta_m}{k_1}\right) e^{ink_1 r}. \quad (3.41)$$

Chapter 3. Neutrino Oscillations with Oscillatory Matter Profiles

where $J_n(z)$ is the Bessel function of the first kind of order n . The Hamiltonian becomes a Rabi oscillation system with an infinite number of Rabi modes:

$$\mathbf{H}^{(R)} = -\frac{\omega_m}{2}\sigma_3 - \frac{1}{2} \sum_{n=-\infty}^{\infty} A_n \begin{pmatrix} 0 & e^{ink_1 r} \\ e^{-ink_1 r} & 0 \end{pmatrix}, \quad (3.42)$$

where

$$A_n = \tan 2\theta_m n k_1 J_n \left(\frac{\lambda_1}{k_1} \cos 2\theta_m \right) \quad (3.43)$$

and $n k_1$ are the amplitude and wavenumber of the n th Rabi mode.¹ In obtaining Eqn. (3.42), I have used the following identity of the Bessel function

$$J_{n-1}(z) + J_{n+1}(z) = \frac{2n}{z} J_n(z). \quad (3.44)$$

Eqn. (3.42) implies an infinite number of resonance conditions

$$\omega_m = n k_1 \quad (n = 1, 2, \dots) \quad (3.45)$$

However, the amplitude of the Rabi mode A_n drops quickly as a function of n because

$$J_n(z) \xrightarrow{z \ll \sqrt{n+1}} \frac{(z/2)^n}{n!} \quad \text{if } n > 0 \quad (3.46)$$

when $\lambda_1/k_1 \ll 1$. For $\lambda_1/k_1 \gtrsim 1$, A_n also becomes small for sufficiently large n because

$$J_n(z) \xrightarrow{n \gg 1} \frac{1}{\sqrt{2\pi n}} \left(\frac{ez}{2n} \right)^n. \quad (3.47)$$

Any real physical system has a finite size l and the Rabi modes with the oscillation

¹A phase in the matter potential would contribute to the phases of the Rabi modes which do not play any role in the resonance for the reason discussed in Sec. 3.1

wavelengths $2\pi/\Omega_n \sim 2\pi/A_n \gtrsim l$ can be ignored even if they are on resonance.

In Sec. 3.3, I have discussed the scenario where the $n = 1$ Rabi mode is on or close to the resonance with $\lambda_1/\omega_m \ll 1$. Using Eqn. (3.46) and identity

$$J_{-n}(z) = (-1)^n J_n(z) \quad (3.48)$$

I obtain

$$A_{\pm 1} \approx \frac{\lambda_1 \sin(2\theta_m)}{2}, \quad (3.49)$$

which agrees with Eqn. (3.27). According to Eqn. (3.16), compared with the case where the first Rabi mode is present, the relative detuning of the Rabi resonance has a change of magnitude

$$\Delta D_{(n)} = \frac{1}{2} \frac{A_n}{A_1} \frac{1}{D_n} \quad (3.50)$$

when another Rabi mode n is present, where D_n is the relative detuning when only the n th Rabi mode is considered. In Table 3.2, I listed the values of A_n/A_1 , D_n , and $\Delta D_{(n)}$ of a few off-resonance Rabi modes for the three numerical examples plotted in Fig. 3.5. One can see that all the off-resonance Rabi modes have very little impact on the resonance which explains why we could ignore the oscillating σ_3 terms in Eqn. (3.26).

3.7 Multi-frequency Matter Profiles Revisited

For a multi-frequency matter profile

$$\lambda(r) = \lambda_0 + \sum_a \lambda_a \cos(k_a r), \quad (3.51)$$

it is straightforward although a little bit tedious to show that the Hamiltonian in the Rabi basis is

$$H^{(R)} = -\frac{\omega_m}{2} \sigma_3 - \frac{1}{2} \sum_{\{n_a\}} A_{\{n_a\}} \begin{pmatrix} 0 & e^{iK_{\{n_a\}}r} \\ e^{-iK_{\{n_a\}}r} & 0 \end{pmatrix}, \quad (3.52)$$

where $\{n_a\}$ stands for a set of arbitrary integers each associating with a particular Fourier mode, and

$$K_{\{n_a\}} = \sum_a n_a k_a \quad (3.53)$$

and

$$A_{\{n_a\}} = \tan(2\theta_m) K_{\{n_a\}} \prod_a J_{n_a} \left(\frac{\lambda_a}{k_a} \cos(2\theta_m) \right). \quad (3.54)$$

are the wavenumber and amplitude of the Rabi mode denoted by $\{n_a\}$, respectively. There are potentially many Rabi modes that approximately satisfy the resonance condition

$$K_{\{n_a\}} = \omega_m. \quad (3.55)$$

However, according to the discussion in Sec. 3.6, the Rabi modes with large $|n_a|$ s have very long oscillation wavelengths and can be ignored even if they are on resonance. The off-resonance Rabi modes with large $|n_a|$ s have very small amplitudes and do not have a significant impact on the resonance either. Therefore, only a finite number of Rabi modes need to be considered for a realistic system.

As an example of a matter profile with multiple frequencies, I will consider the

castle wall profile

$$\lambda(r) = \begin{cases} \Lambda_1 & \text{if } -\frac{X_1}{2} + nX \leq r \leq \frac{X_1}{2} + nX, \\ \Lambda_2 & \text{otherwise,} \end{cases} \quad (3.56)$$

where n is an arbitrary integer, X is the period of the potential, and Λ_1 , Λ_2 , and X_1 are constants. The parametric resonance condition for the castle wall potential has been derived by E. Akhmedov [19]:

$$\frac{\tan(\omega_{m1}X_1/2)}{\tan(\omega_{m2}X_2/2)} = -\frac{\cos 2\theta_{m2}}{\cos 2\theta_{m1}}, \quad (3.57)$$

where

$$\omega_{mi} = \omega_v \sqrt{(\Lambda_i/\omega_v - \cos(2\theta_v))^2 + \sin^2 2\theta_v}, \quad (3.58)$$

$$\theta_{mi} = \frac{1}{2} \arctan \left(\frac{\sin(2\theta_v)}{\cos(2\theta_v) - \Lambda_i/\omega_v} \right) \quad (3.59)$$

and $X_2 = X_1$. To study the parametric resonance with this particular matter profile, I will decompose the profile into a Fourier series:

$$\lambda(r) = \lambda_0 + \sum_{a=1}^{\infty} \lambda_a \cos(k_a r), \quad (3.60)$$

where

$$\begin{aligned} \lambda_0 &= (\Lambda_1 + \Lambda_2)/2, \\ \lambda_a &= \frac{2}{(2a-1)\pi} (-1)^a (\Lambda_1 - \Lambda_2), \\ k_a &= (2a-1)k_1, \\ k_1 &= 2\pi/X, \end{aligned}$$

and I have assumed $X_1 = X_2 = X/2$. As a concrete example, I choose $\Lambda_1 = 0.3\omega_v \cos(2\theta_v)$, $\Lambda_2 = 0.7\omega_v \cos(2\theta_v)$, and $X = 2\pi/\omega_m = 2X_1$. For this particular example, the Rabi mode $\{1, 0, 0, \dots\}$ is on resonance. In Fig. 3.8, I compared the numerical solution to the full equation of motion and that obtained from the Rabi formula in Eqn. (3.9). They agree with each other very well.

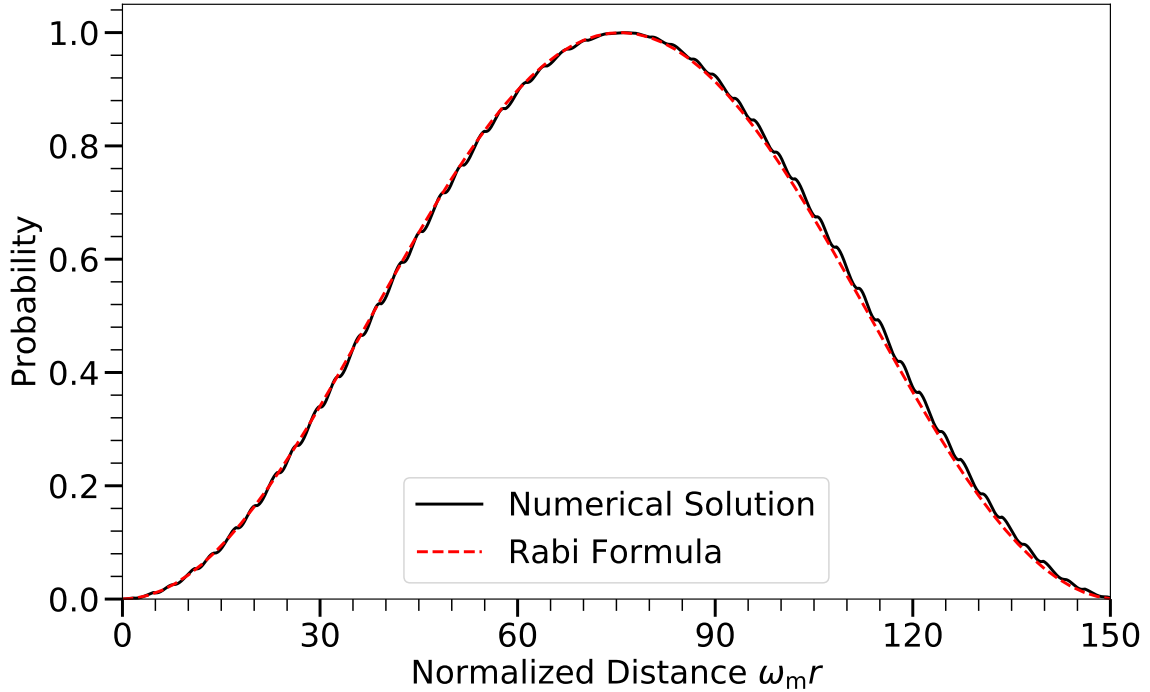

Figure 3.8: The transition probability of the neutrino flavor conversion with a castle wall matter profile as a function of distance r . The period of the castle wall potential X is chosen that the Rabi mode with wavenumber $K = 1$ is on resonance.

In the above example, there are an infinite number of Rabi modes that are on resonance in addition to $\{1, 0, 0, \dots\}$. In principle, one should add the amplitudes of all these resonances modes together in calculating the transition probability with the Rabi formula. However, all the Rabi modes that are on resonance have very tiny amplitudes except $\{1, 0, 0, \dots\}$ (see Table. 3.3). Therefore, they can be neglected in calculations. There are also an infinite number of Rabi modes that are off resonance. In Table. 3.3 I listed some of these Rabi modes with the largest amplitudes. One

$\{n_a\}$	$A_{\{n_a\}}/A_{\{1,0,0,\dots\}}$	$D_{\{n_a\}}$	$\Delta D_{(\{n_a\})}$
$\{-2, 1, 0, \dots\}$	5.4×10^{-4}	0	-
$\{-1, -1, 1, \dots\}$	4.3×10^{-5}	0	-
$\{0, 2, -1, \dots\}$	2.4×10^{-6}	0	-
$\{-1, 0, 0, \dots\}$	1	48	1.0×10^{-2}
$\{0, 1, 0, \dots\}$	0.33	1.5×10^2	1.1×10^{-3}
$\{2, 0, 0, \dots\}$	1.3×10^{-3}	2.4×10^2	2.0×10^{-4}

Table 3.3: The amplitudes and relative detunings of a few Rabi modes $\{n_a\}$ and the changes to the relative detunings of the on-resonance modes due to these Rabi modes if they are off resonance.

can see that the change to the relative detunings $D_{(\{n_a\})}$ of the on-resonance mode $\{1, 0, 0, \dots\}$ due to the presence of the mode $\{n_a\}$ are all very small. As a result, they all have very little impact on the neutrino flavor conversion. This explains the agreement between the numerical solution and the result using the Rabi formula in Fig. 3.8.

3.8 Summary

In this chapter, I have shown that the flavor conversion of a neutrino can be greatly enhanced when it propagates through an oscillatory matter profile when certain resonance conditions are satisfied. This derivation is done from the perspective of Rabi oscillations and is much more physically intuitive than the original derivation by J. Kneller et al. in references [22, 23]. I have shown that, although there can exist an infinite number of Rabi modes that approximately satisfy the resonance condition, only a few of them need to be considered for a real system. I have also derived a criterion when an off-resonance Rabi mode may significantly affect the resonance. Using this criterion I have shown that only a few of the infinite set of off-resonance Rabi modes may contribute to neutrino flavor conversions. Although I have assumed small perturbations on top of a constant matter profile, this approach can be applied to a

Chapter 3. Neutrino Oscillations with Oscillatory Matter Profiles

matter profile with perturbations on top of a smoothly varying background density as have been done by K. Patton et al. in reference [25]. This result may be applicable to the regions in a star where the matter density fluctuates. There can also exist a turbulent matter distribution behind the shock in a core-collapse supernova where this result may be applicable. However, the large neutrino fluxes inside a supernova core may have an even larger impact on neutrino oscillations which I will consider in the next chapter.

Chapter 4

Collective Neutrino Oscillations

Neutrino oscillations in the matter background have well defined linear dynamics as I have discussed in the preceding chapters. In this chapter, I will discuss neutrino oscillations in a dense neutrino medium where the equation of motion becomes nonlinear. One of such examples is the (core-collapse) supernova explosion which releases approximately 10^{58} neutrinos within seconds [26]. The neutrino density inside a supernova can be so large that the neutrino self-interaction potential $H_{\nu\nu}$ to be comparable to or even larger than the matter potential in certain regions [27]. It has been shown that the self-interaction between the neutrinos can cause the neutrino medium to oscillate collectively [11, 28]. The neutrino self-interaction also introduces a new characteristic energy scale which is proportional to the neutrino number density. As a result it is possible that neutrinos can oscillate on distance scales much shorter than the vacuum neutrino oscillation wavelength [29, 30].

In this chapter, I will first review some of the general features of collective neutrino oscillations and introduce the method of linearized flavor stability analysis. I will then discuss the dispersion relations of the collective modes of neutrino oscillations and show that it may or may not be related to the flavor stability of a neutrino gas. Finally, I will demonstrate a preliminary study of a toy model which can be used to understand the neutrino oscillations in the presence of the neutrino halo [31, 32].

4.1 Equation of Motion

The equation of motion for neutrino oscillations with self-interaction is [33]

$$i \frac{d}{dt} \rho = [\mathbf{H}, \rho], \quad (4.1)$$

where the total derivative is

$$\frac{d}{dt} = \partial_t + \mathbf{v} \cdot \nabla, \quad (4.2)$$

and the Hamiltonian is composed of three different terms:

$$\mathbf{H} = \mathbf{H}_v + \mathbf{H}_{\nu\nu}. \quad (4.3)$$

In the above equation, the vacuum Hamiltonian is

$$\mathbf{H}_v = \begin{cases} -\frac{1}{2}\eta\omega_v\sigma_3 & \text{for neutrinos,} \\ \frac{1}{2}\eta\omega_v\sigma_3 & \text{for antineutrinos,} \end{cases}$$

where $\eta = +1$ for the normal neutrino mass hierarchy and -1 for the inverted neutrino mass hierarchy, ω_v is the vacuum oscillation frequency of the neutrino or antineutrino.

The neutrino self-interaction is more complicated and can be written as

$$\mathbf{H}_{\nu\nu} = \sqrt{2}G_F \int \frac{E'^2 dE'}{8\pi^3} d\Gamma_{\mathbf{v}'} [n(E', \mathbf{v}')\rho(E', \mathbf{v}') - \bar{n}(E', \mathbf{v}')\bar{\rho}(E', \mathbf{v}')] (1 - \mathbf{v} \cdot \mathbf{v}'), \quad (4.4)$$

where $d\Gamma_\nu$ is the differential solid angle, $n(E, \mathbf{v})$ and $\rho(E, \mathbf{v})$ are the number density and the flavor density matrix of the neutrino with energy E and velocity \mathbf{v} , and $\bar{n}(E, \mathbf{v})$ and $\bar{\rho}(E, \mathbf{v})$ are the corresponding quantities of the antineutrino.

The presence of the neutrino self-interaction potential makes the equation of motion (4.1) nonlinear, and many interesting phenomena arise because of it. For exam-

Chapter 4. Collective Neutrino Oscillations

ple, a dense neutrino medium can experience synchronized oscillations during which all the neutrinos and antineutrinos oscillate with the same frequency [11, 34–36]. To see this, I will consider an isotropic and homogeneous neutrino gas and use the flavor isospin picture discussed in Sec. 2.4. The flavor isospin \vec{s} of the neutrino is defined by

$$\rho = \frac{1}{2} + \vec{s} \cdot \vec{\sigma}. \quad (4.5)$$

The equation of motion of the flavor isospin is

$$\dot{\vec{s}} = \vec{s} \times (\vec{H}_v + \vec{H}_{\nu\nu}), \quad (4.6)$$

where

$$\vec{H}_v = \omega_v \begin{pmatrix} -\sin 2\theta_v \\ 0 \\ \cos 2\theta_v \end{pmatrix} = \omega_v \vec{B}, \quad (4.7)$$

and

$$\vec{H}_{\nu\nu} = \frac{\sqrt{2}G_F}{2\pi^2} \int E'^2 dE' n(E') \vec{s}(E'). \quad (4.8)$$

Here for simplicity I have assumed $n_e = 0$ and $\bar{n} = 0$. When the neutrino density is very large, $\vec{H}_{\nu\nu}$ dominates over \vec{H}_v in Eqn. (4.6), and \vec{s} precesses about $\vec{H}_{\nu\nu}$ rapidly. Meanwhile, the total flavor isospin

$$\vec{S} = \int dE' f(E') \vec{s}(E') \quad (4.9)$$

precesses about \vec{H}_v slowly with a mean oscillation frequency $\langle\omega_v\rangle$, where

$$f(E) = \frac{E^2 n(E)}{\int E'^2 dE' n(E')} \quad (4.10)$$

is the energy distribution of the neutrino. To see this, one can multiply Eqn. (4.6)

by $f(E)$ and integrate over E which gives

$$\dot{\vec{S}} = \int dE f(E) \vec{s}(E) \times \omega_v \vec{B} \quad (4.11)$$

$$\rightarrow \int dE f(E) \left[\frac{\vec{s}(E) \cdot \vec{S}}{|\vec{S}|^2} \vec{S} \right] \times \omega_v \vec{B} \quad (4.12)$$

$$= \langle \omega_v \rangle \vec{S} \times \vec{B}, \quad (4.13)$$

where

$$\langle \omega_v \rangle = \int dE f(E) \left[\frac{\vec{s}(E) \cdot \vec{S}}{|\vec{S}|^2} \right] \omega_v. \quad (4.14)$$

In the above equation I have replaced flavor isospin \vec{s} with its projection along the direction of \vec{S} because its precession about \vec{S} is much faster than the precession of \vec{S} about \vec{B} .

4.2 Two-Beam Model and Flavor Instabilities

During the synchronized flavor transformation, the whole neutrino medium behaves as if there was a single neutrino oscillating with the mean frequency $\langle \omega_v \rangle$ in vacuum. Under certain conditions, the neutrino self-interaction potential can cause the neutrino medium to evolve in a way completely different than vacuum oscillations. I will illustrate this phenomenon using the two-beam neutrino model.

In the two-beam model, neutrinos and antineutrinos are constantly emitted in two different directions from a plane which we assume to be the x - y plane. I define the emission angles of the neutrino beams θ_1 and θ_2 to be inside the plane spanned by the velocity vectors of the two neutrino beams (see Fig. 4.1). I will assume that the neutrino emission plane is homogeneous and that the neutrino and antineutrino have the same density n in the emission plane. I will also assume that the matter density

vanishes everywhere in space.

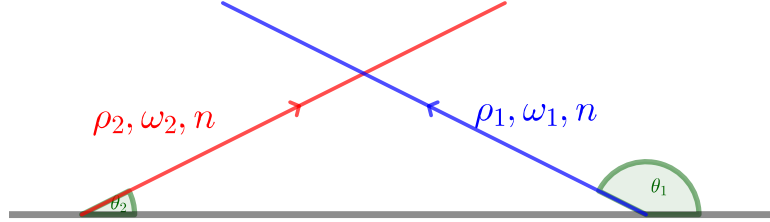

Figure 4.1: The geometry of two-beam model. The i th ($i = 1, 2$) neutrino beam has emission angle θ_i , vacuum oscillation frequency ω_i and density matrix ρ_i . Both neutrino beams have the same number flux n .

The Hamiltonian of the i th neutrino beam in the vacuum basis is

$$H_i = -\frac{\omega_i}{2}\sigma_3 + \mu(\rho_1 - \rho_2), \quad (4.15)$$

where $\omega_1 = \eta\omega_v$ for the neutrino beam and $\omega_2 = -\eta\omega_v$ for the antineutrino beam,

$$\mu = \sqrt{2}G_F(1 - \cos(\theta_1 - \theta_2))n \quad (4.16)$$

is the neutrino self-interaction potential.

I will assume that the neutrino and antineutrino are emitted in the pure electron flavor at $z = 0$. I will also assume the vacuum mixing angle $\theta_v \ll 1$. Therefore, the flavor density matrix of the i th neutrino beam in the vacuum basis at $z = 0$ is

$$\rho_i(z = 0) \approx \begin{pmatrix} 1 & \epsilon_i(0) \\ \epsilon_i^*(0) & 0 \end{pmatrix}, \quad (4.17)$$

where

$$\epsilon_i(0) = \sin(2\theta_v) \ll 1. \quad (4.18)$$

I solve the two-beam model numerically with $\epsilon_i = 10^{-3}$ and $\eta = -1$. The solution is shown in Fig. 4.2. When $\omega_v z \ll 1$, the flavor isospin of the neutrino stays in the electron flavor state, i.e., in the direction of third axis \vec{e}_3 in the flavor space (see the left panel of Fig. 4.2). Accordingly, the electron flavor survival probability $P_{\nu_e} \approx 1$ at small z but falls down rapidly at a certain value of z (see the right panel of Fig. 4.2). Then both the flavor isospin and P_{ν_e} come back to their original positions until they fall down again. The flavor isospin of the antineutrino follows a similar pattern but is in a different direction. This flavor transformation phenomenon is clearly different from the vacuum oscillations shown in Fig. 2.1.

To gain a deeper understanding of the collective oscillation phenomenon, I will focus on the linear regime where $|\epsilon_i(z)| \ll 1$. The equation of motion is linearized in this regime and becomes

$$i\partial_z \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \end{pmatrix} = \begin{pmatrix} \mu + \eta\omega_v & -\mu \\ \mu & -\eta\omega_v - \mu \end{pmatrix} \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \end{pmatrix}. \quad (4.19)$$

This equation has two normal modes which correspond to the collective modes of neutrino oscillations:

$$\begin{pmatrix} \epsilon_1(z) \\ \epsilon_2(z) \end{pmatrix} = \begin{pmatrix} Q_{1\pm} \\ Q_{2\pm} \end{pmatrix} e^{iK_{z\pm}z}, \quad (4.20)$$

where $(Q_{1\pm}, Q_{2\pm})^T$ are the eigenvectors of the two normal modes, and

$$K_{z\pm} = \pm\sqrt{\omega_v(\omega_v + 2\eta\mu)} \quad (4.21)$$

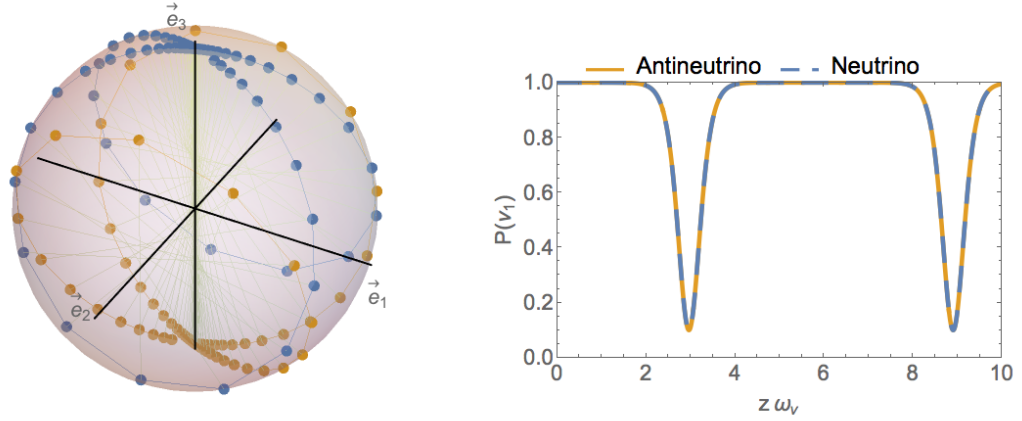

Figure 4.2: The numerical solution to the two-beam model. The left panel shows the position of the flavor isospins of the neutrino beam (in blue) and the antineutrino beam (in orange). The right panel shows the probabilities as functions of distance z (in unit of ω_ν^{-1}) for the neutrino and antineutrino to remain in the $|\nu_1\rangle$ and $|\bar{\nu}_1\rangle$ states, which are the same as the survival probabilities of the electron flavor when the mixing angle $\theta_\nu \ll 1$. In this calculation, the emission angles are $\theta_1 = 5\pi/6$ and $\theta_2 = \pi/6$, the neutrino self-interaction potential is $\mu = 5\omega_\nu$, and the neutrino mass hierarchy is inverted.

are the wavenumbers of the corresponding modes. For the normal mass hierarchy, $\eta = 1$, and $K_{z\pm}$ are always real. In this case, the electron flavor probability P_{ν_e} is always approximately 1. However, for the inverted neutrino mass hierarchy, $\eta = -1$, and $K_{z\pm}$ are imaginary when $\mu > \omega_\nu/2$. The normal mode with wavenumber $K_{z-} = -i\sqrt{\omega_\nu(2\mu - \omega_\nu)}$ is a runaway solution which explains the rapid decrease of P_{ν_e} in Fig. 4.2.

4.3 Dispersion Relations

In the two-beam model, I have assumed the neutrino flavor density matrix $\rho(z)$ depends on z only. For the neutrino medium in a real physical environment, $\rho(t, \mathbf{r})$ is

Chapter 4. Collective Neutrino Oscillations

a function of both time t and spatial coordinate \mathbf{r} . The collective mode a of neutrino oscillations takes the form

$$\epsilon_i(t, \mathbf{r}) = Q_i^{(a)} e^{i(\Omega_a t - \mathbf{K}_a \cdot \mathbf{r})} \quad (4.22)$$

where index i denotes the species and the propagation direction of the neutrino, and Ω_a and \mathbf{K}_a are the oscillation frequency and wavevector of the corresponding collective mode, respectively. In this section, I will review the dispersion relations between Ω_a and \mathbf{K}_a discussed by I. Izaguirre, G. Raffelt, and I. Tamborra in reference [37].

The equation of motion for the flavor transformation of a dense neutrino medium in flavor basis is

$$i(\partial_t + \mathbf{v} \cdot \nabla)\rho = \left[\frac{\lambda}{2} \sigma_3 + \mathbf{H}_{\nu\nu}, \rho \right], \quad (4.23)$$

where I have ignored the vacuum Hamiltonian. This is because the vacuum oscillation frequency of the neutrino

$$\begin{aligned} \omega_v &= \frac{\Delta m^2}{2E} \sim \frac{2\pi}{10\text{km}} \left(\frac{\Delta m_{32}^2}{2.5 \times 10^{-3} \text{eV}^2} \right) \left(\frac{10\text{MeV}}{E} \right) \\ &\sim \frac{2\pi}{330\text{km}} \left(\frac{\Delta m_{12}^2}{7.5 \times 10^{-5} \text{eV}^2} \right) \left(\frac{10\text{MeV}}{E} \right) \end{aligned}$$

is much smaller than the neutrino potential

$$\mu = \sqrt{2} G_F n \sim \frac{1}{0.01\text{km}} \left(\frac{100\text{km}}{R} \right)^2 \left(\frac{1\text{MeV}}{E} \right) \left(\frac{L}{10^{50} \text{erg} \cdot \text{s}^{-1}} \right),$$

where E is the typical energy of the supernova neutrino, n is the total number density of the neutrino, R is the distance from the center of the supernova, and L is the total luminosity of the neutrino. In Eqn. (4.23),

$$\mathbf{H}_{\nu\nu} = \sqrt{2} G_F \iint d\Gamma' v^\mu v'_\mu \int \frac{E'^2 dE'}{8\pi^3} ((n'_{\nu_e} - n'_{\nu_x})\rho' - (n'_{\bar{\nu}_e} - n'_{\bar{\nu}_x})\bar{\rho}'), \quad (4.24)$$

Chapter 4. Collective Neutrino Oscillations

where

$$v^\mu = (1, \mathbf{v})^T = (1, \sin \theta \cos \phi, \sin \theta \sin \phi, \cos \theta)^T \quad (4.25)$$

is the four velocity of the neutrino and the primed quantities such as $\rho' = \rho_{\mathbf{v}'}(t, \mathbf{r})$ depend on the primed physical variable \mathbf{v}' . Without the vacuum Hamiltonian, the equation of motion for the antineutrino is the same as Eqn. (4.23).

In the supernova, the fluxes of non-electron-flavor neutrinos are approximately the same. It is convenient to define the electron lepton number (ELN) as [37]

$$G(\mathbf{v}) = \sqrt{2}G_F \int \frac{E'^2 dE'}{8\pi^3} [n_{\nu_e}(\cos \theta', \phi', E') - n_{\bar{\nu}_e}(\cos \theta', \phi', E')]. \quad (4.26)$$

I will perform the linear stability analysis as in Sec. 4.2. For this purpose, I will assume that the density matrices of the neutrino and antineutrino have the form

$$\rho_{\mathbf{v}}(t, \mathbf{r}) = \bar{\rho}_{\mathbf{v}}(t, \mathbf{r}) = \begin{pmatrix} 1 & \epsilon_{\mathbf{v}}(t, \mathbf{r}) \\ \epsilon_{\mathbf{v}}^*(t, \mathbf{r}) & 0 \end{pmatrix}, \quad (4.27)$$

where $|\epsilon_{\mathbf{v}}(t, \mathbf{r})| \ll 1$. Plugging this into the equation of motion, I obtain the linearized equation of motion

$$i(\partial_t + \mathbf{v} \cdot \nabla)\epsilon = v^\mu \Phi_\mu \epsilon - \int d\Gamma' v^\mu v'_\mu G(\mathbf{v}') \epsilon', \quad (4.28)$$

where

$$\Phi_\mu = \left(- \int d\Gamma' G(\mathbf{v}'), \int d\Gamma' \mathbf{v}' G(\mathbf{v}') \right)^T. \quad (4.29)$$

Assuming the solution in Eqn. (4.22), I obtain

$$v^\mu k_\mu Q_{\mathbf{v}} = - \int d\Gamma' v^\mu v'_\mu G(\mathbf{v}') Q_{\mathbf{v}'}, \quad (4.30)$$

where

$$k_\mu = \begin{pmatrix} \omega \\ \mathbf{k} \end{pmatrix} = \begin{pmatrix} \Omega - \Phi_0 \\ \mathbf{K} - \mathbf{\Phi} \end{pmatrix}. \quad (4.31)$$

From Eqn. (4.30) I have the formal solution

$$Q_{\mathbf{v}} = -\frac{v^\mu a_\mu}{v^\alpha k_\alpha}, \quad (4.32)$$

where

$$a^\nu = \int d\Gamma_{\mathbf{v}} G(\mathbf{v}) v^\nu Q_{\mathbf{v}}. \quad (4.33)$$

Substituting Eqn. (4.32) into Eqn. (4.30), I obtain

$$v_\mu \Pi^\mu_\nu a^\nu = 0, \quad (4.34)$$

where

$$\Pi^\mu_\nu = \delta^\mu_\nu + \int d\Gamma G(\mathbf{v}) \frac{v^\mu v_\nu}{\omega - \mathbf{k} \cdot \mathbf{v}}. \quad (4.35)$$

The dispersion relation between ω and \mathbf{k} is obtained by solving the characteristic equation [37]

$$\det(\Pi^\mu_\nu) = 0 \quad (4.36)$$

since we are looking for non-trivial solutions of a^ν .

4.4 Flavor Instabilities and Dispersion-Relation Gaps

One can find the flavor instabilities of a neutrino medium by solving the dispersion relations (DR) between ω and \mathbf{k} from Eqn. (4.36). A negative imaginary component of ω indicates a flavor instability in time, and a positive imaginary component of $\mathbf{k} \cdot \hat{\mathbf{z}}$ indicates a flavor instability in the $+z$ direction. I. Izaguirre et al. conjectured that

Chapter 4. Collective Neutrino Oscillations

the flavor instabilities exist in the gaps between the real branches of the dispersion relations [37]. In the first part this section I will first explain this conjecture, and in the second part I will show that this conjecture is actually incorrect.

4.4.1 Conjecture of the Relation between Flavor Instabilities and DR Gaps

I will consider a model with neutrinos emitted symmetrically about the z axis. For this model, the characteristic equation (4.36) reduces to

$$\det \left(\omega \mathbf{I} + \frac{1}{2} \begin{pmatrix} I_0 & 0 & 0 & -I_1 \\ 0 & -\frac{1}{2}(I_0 - I_2) & 0 & 0 \\ 0 & 0 & -\frac{1}{2}(I_0 - I_2) & 0 \\ I_1 & 0 & 0 & -I_2 \end{pmatrix} \right) = 0, \quad (4.37)$$

where \mathbf{I} is the rank-4 identity matrix and

$$I_m = \int_{-1}^1 du G(u) \frac{u^m}{1 - u/v_{\text{ph}}}. \quad (4.38)$$

where $u = \cos \theta$, and $v_{\text{ph}} = \omega/k$. Here I have assumed $\mathbf{k} = k\hat{\mathbf{z}}$. Eqn. (4.37) is satisfied if

$$\omega = -\frac{1}{4} \left(I_0 - I_2 \pm \sqrt{(I_0 + I_2 - 2I_1)(I_0 + I_2 + 2I_1)} \right) \quad (4.39)$$

or

$$\omega = \frac{1}{4} (I_0 - I_2). \quad (4.40)$$

I will call the solutions to Eqn. (4.39) the symmetric solutions (SS+ and SS− for the solutions to ω with the + and − signs) because they preserve the axial symmetry about the z axis. I will call the solutions to Eqn. (4.40) the asymmetric solutions (AS) because they break the axial symmetry.

Chapter 4. Collective Neutrino Oscillations

To illustrate the conjecture by I. Izaguirre et al., I will consider the two-angle model where the neutrinos are emitted with two zenith angles θ_1 and θ_2 . The ELN of the two-angle model is

$$G(u) = \mu \sum_{i=1,2} g_i \delta(u - u_i), \quad (4.41)$$

where $\mu = \sqrt{2}G_F n$ is proportional to the neutrino number density n , g_i are real numbers, and $u_i = \cos \theta_i$ ($i = 1, 2$). For any real k , the characteristic equations (4.39) and (4.40) are both quadratic equations of ω with two solutions. In Fig. 4.3, I show the SS and AS of the dispersion relations $\omega(k)$ with $u_1 = -0.6$, $u_2 = 0.6$ and $g_1 = g_2 = 1$. In either case, both solutions $\omega(k)$ to the characteristic equations are real. However, there exist gaps between the DR curves where there is no real solution $k(\omega)$ for given real values of ω . Because the characteristic equations are also quadratic equations of k for any given real value of ω , a pair of complex solutions $k(\omega) = k_R(\omega) \pm ik_I(\omega)$ exist in the DR gap of ω (see Fig. 4.3).

The observation of the result of the two-angle model leads I. Izaguirre et al. to conjecture that the flavor instabilities are associated with the DR gaps. They also studied the dispersion relations using a continuous ELN distribution from a 1D supernova simulation¹ which are reproduced in Fig. 4.4.

4.4.2 Refutation of the Conjecture

The association of the flavor instability in space, i.e., $k_I(\omega) \neq 0$, with a DR gap in ω seems fortuitous for the two-angle model. As I explained previously, for the two-angle model, the characteristic equations are quadratic equation of k for any given

¹The data is from the Garching Core-Collapse Supernova Archive at <http://wwwmpa.mpa-garching.mpg.de/ccsnarchive/archive.html>

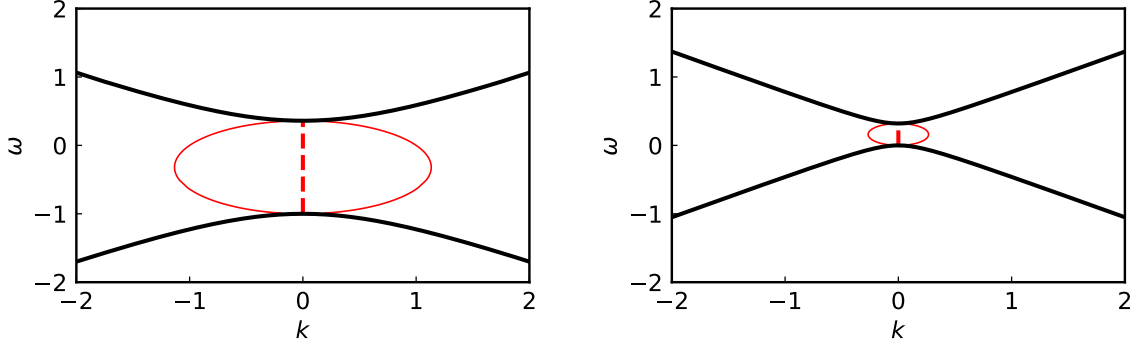

Figure 4.3: The SS (left) and AS (right) of the dispersion relations for the two-angle model. The thick black curves represent $\omega(k)$ for real k . The red dashed and thin solid curves are $k_R(\omega)$ and $k_R(\omega) \pm k_I(\omega)$ for real ω within the DR gap of ω . Both ω and k are measured in terms of the neutrino potential μ .

ω . Therefore there always exists a pair of complex solutions between the DR gap in ω . This is not the case when the neutrinos are emitted with more than two zenith angles.

In Fig. 4.5, I show the dispersion relations of a three-angle model with ELN

$$G(u) = \frac{\mu}{2}\delta(u + 0.1) + \mu\delta(u - 0.4) + \mu\delta(u - 0.6). \quad (4.42)$$

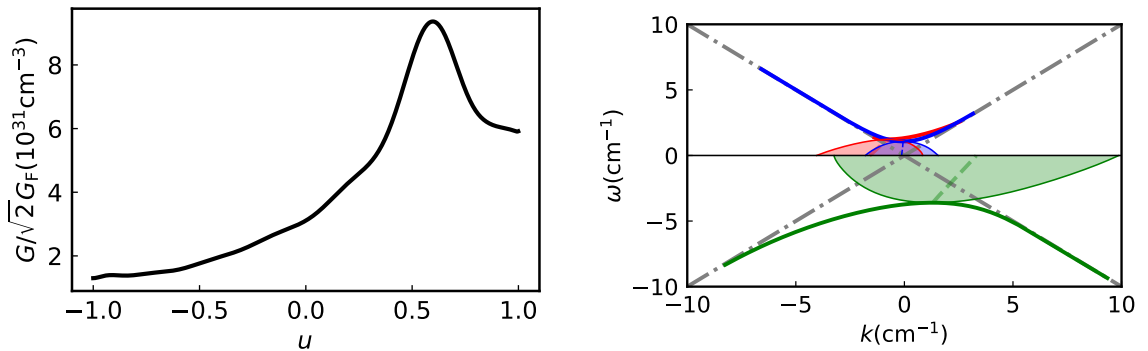

Figure 4.4: The SS+ (green), SS- (blue) and AS (red) of the dispersion relations (right panel) for a net electron flavor neutrino density distribution $n_{\nu_e}(u) - n_{\bar{\nu}_e}(u)$ obtained from a 1D supernova simulation by the Garching group (left panel). The thick solid curves represent the dispersion relations when both ω and k are real. The dashed curves represent $k_R(\omega)$ in the DR gap of ω , and the thin solid curves (bounding the shaded regions) are $k_R(\omega) \pm k_I(\omega)$.

Chapter 4. Collective Neutrino Oscillations

For this model, there exist complex solutions of $k(\omega)$ even though there is no DR gap in ω . This is because the characteristic equations are cubic equations of k for given ω which admit three solutions. In certain ranges of ω there is only one real solution of $k(\omega)$. The other two solutions must be complex which indicates flavor instabilities in space.

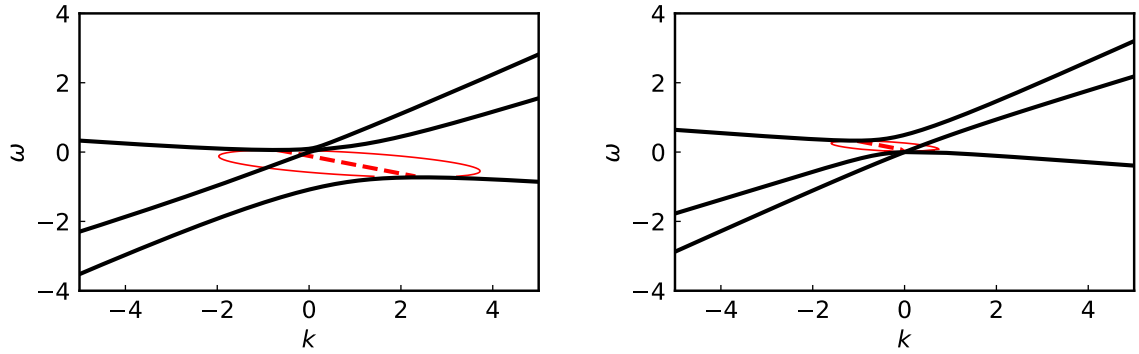

Figure 4.5: The same as Fig. 4.3 but for the three-angle model described in the text.

The conjecture between the flavor instabilities and DR gaps does not work for the models with a continuous ELN distribution $G(u)$ either. In Fig. 4.6 I show the dispersion relations for a step-like distribution

$$G(u) = \begin{cases} -0.1 & \text{if } -1 < u < -0.3, \\ 1 & \text{otherwise.} \end{cases} \quad (4.43)$$

One sees that, for this model, the SS+ and SS− solutions merge into a continuous DR curve so that there is no gap in ω . However, there do exist complex solutions $k(\omega)$ for certain values of ω .

As shown in Fig. 4.4 and Fig. 4.6, AS dispersion relations $k(\omega)$ appear only in the region where $\omega > 0$. This can be proved analytically as follows. Suppose there exist dispersion relations $k(\omega) = k_R(\omega) + ik_I(\omega)$ for $\omega \rightarrow 0$. Using the Sokhotski–Plemelj

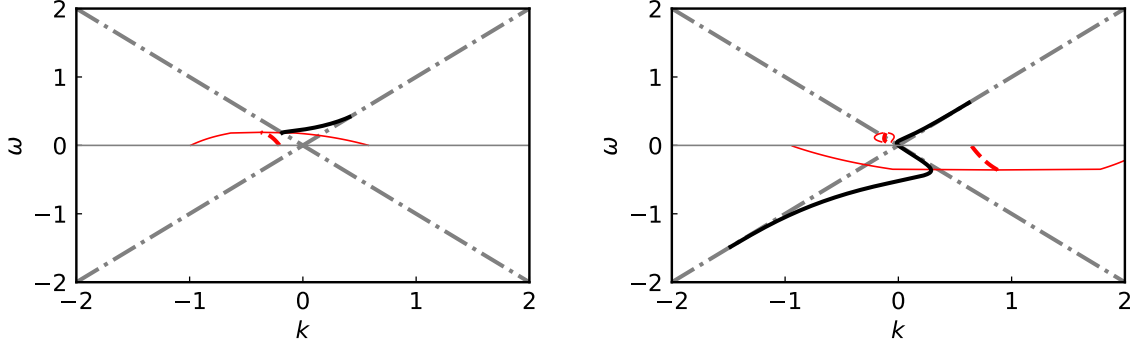

Figure 4.6: The same as Fig. 4.3 but for the ELN distribution in Eqn. (4.43).

theorem, I can rewrite the characteristic equation

$$k = \frac{1}{4} \int du G(u) \frac{1 - u^2}{\omega/k - u}. \quad (4.44)$$

as

$$k_{\text{R}} = \frac{1}{4} \left(\mathcal{P} \int du G(u) \frac{1 - u^2}{-u} \right) \quad (4.45a)$$

$$|k_{\text{I}}| = \frac{\pi}{4} G(0) \text{Sign}(\omega), \quad (4.45b)$$

where \mathcal{P} denotes the principal value of the integral. As long as $G(0) \neq 0$, ω must have the same sign as $G(0)$ which implies that $k(\omega)$ exists only on one side of the $\omega = 0$ axis. For the two scenarios depicted in Fig. 4.4 and Fig. 4.6, $G(0) > 0$ and $k(\omega)$ exist only in the upper half plane of ω . This shows that, at least near $\omega = 0$, the absence of a DR $\omega(k)$, i.e., a “gap” in ω , is not always associated with the flavor instabilities in space.

Eqn. (4.45) can be used to determine the values of k_{R} and k_{I} in the limit of $\omega \rightarrow 0$ for the AS branch of the dispersion relations. One can apply the same method to the

SS branches which gives

$$\begin{aligned} & (4k_R - J_{-1} + J_1)^2 - (\text{Sign}(\omega k_I) \pi G(0) + 4k_I)^2 \\ &= - (J_{-1} + J_1) \pi \text{Sign}(\omega k_I) G(0) \end{aligned} \quad (4.46)$$

and

$$|k_I| = -\frac{\pi}{4} G(0) \text{Sign}(\omega) \left(1 \pm \frac{J_{-1} + J_1}{4k_R - J_{-1} + J_1} \right), \quad (4.47)$$

where

$$J_n = \mathcal{P} \int G(u) u^n du, \quad (4.48)$$

and the $+$ and $-$ signs are for SS+ and SS−, respectively. Eqn. (4.46) and Eqn. (4.47) show that $k(\omega)$ exists on both sides of the $\omega = 0$ axis but may be different for SS+ and SS−.

4.5 Neutrino Oscillations with Reflected Fluxes

Most of the researches on supernova neutrino oscillations assumed that neutrinos are emitted from the spherical surface of a neutron star and that they are free streaming. In the real supernova environment, however, a small amount of neutrinos can be scattered back towards the neutron star. J. Cherry et al. showed that the “neutrino halo” formed by the scattered neutrino fluxes can change the neutrino self-interaction potential dramatically which may have an impact on neutrino oscillations in the supernova [32]. In the section, I describe a toy model which can be used to explore the effect of the scattered neutrino fluxes on neutrino oscillations.

4.5.1 Two-Beam Model with Reflection

I will consider the two-beam model depicted in Fig. 4.1 but with a “neutrino mirror” at $z = L$ that partially reflects the neutrino beams backward without changing their flavor content. The equations of motion for neutrino oscillations in this model are

$$i \sin \theta_i \partial_z \rho_i = [\mathbf{H}_i, \rho_i] \quad (i = 1, 2, 3, 4) \quad (4.49)$$

where beams 1 and 2 contain neutrinos and antineutrinos, beams 3 and 4 are the reflected fluxes of 1 and 2, respectively, with $\theta_3 = \theta_1$ and $\theta_4 = \theta_2$. The Hamiltonians in the vacuum mass basis are

$$\mathbf{H}_1 = -\eta\omega_v\sigma_3 + \mu(-\alpha\chi_-\rho_2 - \alpha\chi_+R\rho_4 + \chi_1R\rho_3), \quad (4.50)$$

$$\mathbf{H}_2 = \eta\omega_v\sigma_3 + \mu(\chi_-\rho_1 - \alpha\chi_2R\rho_4 + \chi_+R\rho_3), \quad (4.51)$$

$$\mathbf{H}_3 = -\eta\omega_v\sigma_3 + \mu(-\alpha R\chi_-\rho_4 - \alpha\chi_+\rho_2 + \chi_1\rho_1), \quad (4.52)$$

$$\mathbf{H}_4 = \eta\omega_v\sigma_3 + \mu(R\chi_-\rho_3 + \chi_+\rho_1 - \alpha\chi_2\rho_2), \quad (4.53)$$

where $\mu = \sqrt{2}G_F n_1$ with n_1 being the number flux of beam 1, $\alpha = n_2/n_1$, R is the reflection coefficient of the “neutrino mirror”, and

$$\chi_+ = 1 - \cos(\theta_1 + \theta_2), \quad (4.54)$$

$$\chi_- = 1 - \cos(\theta_1 - \theta_2), \quad (4.55)$$

$$\chi_1 = 1 - \cos(2\theta_1), \quad (4.56)$$

$$\chi_2 = 1 - \cos(2\theta_2). \quad (4.57)$$

4.5.2 Relaxation Method

I developed a relaxation method to solve the two-beam model with reflection numerically. For the purpose of illustrating the algorithm, I denote the Hamiltonian using its components in flavor space:

$$H = - \sum_i \frac{H_i}{2} \sigma_i. \quad (4.58)$$

At position z , the evolution operator $U(\Delta l, z)$ is

$$U(\Delta l, z) = \cos\left(\frac{H\Delta l}{2}\right) \mathbf{I} + i \left(\frac{H_1}{H} \sigma_1 + \frac{H_2}{H} \sigma_2 + \frac{H_3}{H} \sigma_3 \right) \sin\left(\frac{H\Delta l}{2}\right) \quad (4.59)$$

where Δl is the propagation distance along the neutrino trajectory between z and the new position z' , and

$$H = \sqrt{H_1^2 + H_2^2 + H_3^2}. \quad (4.60)$$

Then I calculate the density matrix at z' as

$$\rho(z') = \mathcal{F}(H(z), \rho(z), \Delta l) \quad (4.61)$$

$$= U(\Delta l, z) \rho(z) U^\dagger(\Delta l, z) \quad (4.62)$$

$$= \frac{1}{4} \sum_j \left[\cos(H\Delta l) \rho_j - \frac{2}{H^2} \sin^2\left(\frac{H\Delta l}{2}\right) \sum_i H_i \rho_i H_j \right] \sigma_j. \quad (4.63)$$

I discretize the z axis into N bins with $\Delta z = L/N$ and $z_n = n\Delta z$ ($n = 0, 1, \dots, N$).

I use the evolution operator $U_a(\Delta l, z)$ and the following iteration algorithm until I achieve numerical convergence.

for all a , n : *#a is the beam index; n is the position index*

$$\rho_a^0(z_n) = 0$$

for all a :

```

 $\rho_a^0(z_0) = [ [1, \epsilon_a], [\epsilon_a^*, 0] ]$ 
j = 0 #j is the iteration index
do:
  for a = 1, 2 and n < N:
     $\rho_a^{j+1}(z_{n+1}) = \mathcal{F}(H_a^j(z_n), \rho_a^j(z_n), \Delta z / \sin \theta_a)$ 
  for a = 3, 4 and n > 0:
     $\rho_a^{j+1}(z_{n-1}) = \mathcal{F}(H_a^j(z_n), \rho_a^j(z_n), \Delta z / \sin \theta_a)$ 
  j = j + 1
while  $|\rho^{j+1} - \rho^j| > \text{error tolerance}$ 

```

To speed up the calculations, I have parallelized the above algorithm with OpenMP.

4.5.3 Validation of the Relaxation Method with Relected Single-Neutrino-Beam

As a check to the relaxation algorithm discussed in the previous subsection, I apply it to the single-beam model with reflection, i.e., $\theta_1 = \pi/2$ and $\alpha = 0$. As the first step of the validation of the numerical code, I compare the numerical and analytical results for the vacuum oscillations case with $R \rightarrow 0$ and the normal neutrino mass hierarchy. The results are shown in Fig. 4.7.

To further validate the numerical code, I apply the linearized flavor stability analysis to the single-beam model with $R > 0$ and compare it with the numerical results. The equation of motion in the linearized regime is

$$i\partial_z \begin{pmatrix} \epsilon_F \\ \epsilon_B \end{pmatrix} = \begin{pmatrix} -\eta\omega_v + R\mu' & -R\mu' \\ \mu' & \eta\omega_v - \mu' \end{pmatrix} \begin{pmatrix} \epsilon_F \\ \epsilon_B \end{pmatrix}, \quad (4.64)$$

where $\mu' = 2\mu$, and ϵ_F and ϵ_B are the off-diagonal elements of ρ_1 and ρ_3 , respectively.

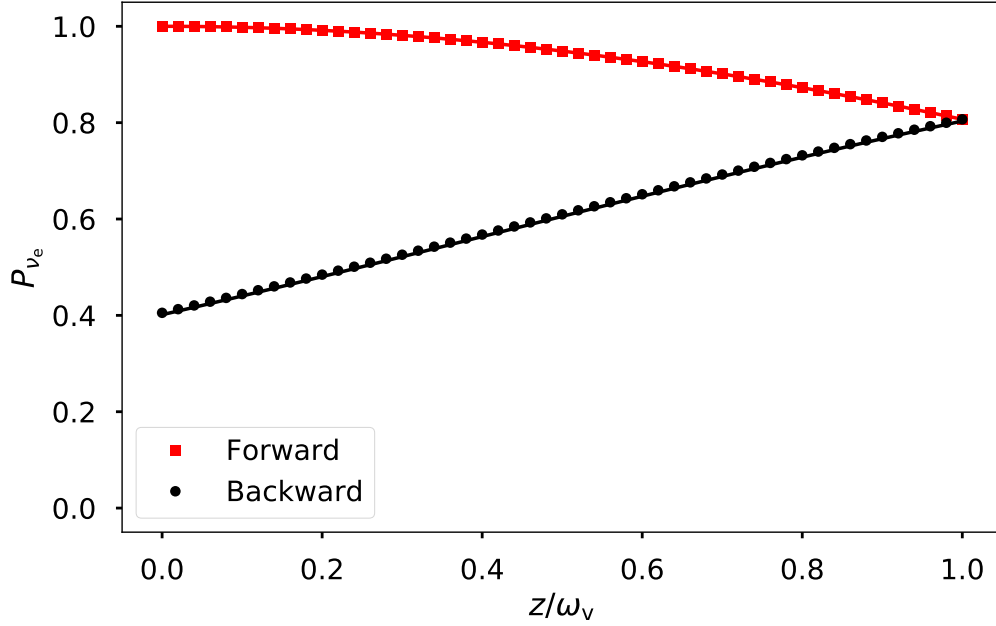

Figure 4.7: The validation of the numerical code for the single-beam model with $R \rightarrow 0$ and $L = 1/\omega_\nu$. The markers and the continuous curves represent the numerical and analytical results, respectively.

This equation can be easily solved. The neutrino gas has two collective modes with oscillation frequencies

$$\Omega_{\pm} = \frac{1}{2}[(R - 1)\mu' \pm \sqrt{\Delta}], \quad (4.65)$$

where

$$\Delta = (1 - R)^2 \mu'^2 - 4\mu' \eta \omega_\nu (1 + R) + 4\omega_\nu^2. \quad (4.66)$$

The corresponding eigenvectors are

$$V_{\pm} = \frac{1}{2\mu'} \begin{pmatrix} -2\eta\omega_\nu + \mu'(1 + R) \pm \sqrt{\Delta} \\ 2\mu' \end{pmatrix}. \quad (4.67)$$

Chapter 4. Collective Neutrino Oscillations

The general solution to the equation of motion is

$$\begin{pmatrix} \epsilon_F(z) \\ \epsilon_B(z) \end{pmatrix} = C_+ V_+ e^{-i\Omega_+ z} + C_- V_- e^{-i\Omega_- z}, \quad (4.68)$$

where C_\pm are constants. Using the fact that $\epsilon_F(L) = \epsilon_B(L)$ at the “neutrino mirror”, I obtain

$$\frac{C_+}{C_-} = e^{-i(\Omega_- - \Omega_+)L} \frac{\sqrt{\Delta} + 2\eta\omega_v + \mu'(1-R)}{\sqrt{\Delta} - 2\eta\omega_v - \mu'(1-R)}. \quad (4.69)$$

Combining Eqn. (4.68) and Eqn. (4.69) I obtain

$$\begin{pmatrix} \epsilon_F(z) \\ \epsilon_B(z) \end{pmatrix} = C_- e^{-i\Omega_- L} \begin{pmatrix} \frac{\sqrt{\Delta} + 2\eta\omega_v + \mu'(1-R)}{\sqrt{\Delta} - 2\eta\omega_v - \mu'(1-R)} V_+ e^{-i\Omega_+(z-L)} + V_- e^{-i\Omega_-(z-L)} \end{pmatrix}. \quad (4.70)$$

Since $\Delta < 0$ when there exist flavor instabilities in the neutrino gas, I define $i\delta = \sqrt{\Delta}$. Therefore,

$$\begin{aligned} |\epsilon_F| \propto & |(2\eta\omega_v + \mu'(1-R) + i\delta)(-2\eta\omega_v + \mu'(1+R) + i\delta)e^{\delta(z-L)} \\ & + (-2\eta\omega_v - \mu'(1-R) + i\delta)(-2\eta\omega_v + \mu'(1+R) - i\delta)e^{-\delta(z-L)}|, \end{aligned} \quad (4.71)$$

which can be simplified as

$$|\epsilon_F| \propto A + B \cosh(2\delta(L-z)) \quad (4.72)$$

with

$$A = 8\mu'^2(\mu' - R - 2\eta\omega_v)^2 + 8\mu'^2\Delta, \quad (4.73)$$

$$B = 8\mu'^2(\mu' - R - 2\eta\omega_v)^2 - 8\mu'^2\Delta. \quad (4.74)$$

Chapter 4. Collective Neutrino Oscillations

The only z dependent term in Eqn. (4.72) is $\cosh(2\delta(L - z))$, which decreases within $[0, L]$. In addition,

$$\left. \frac{d\epsilon_F}{dz} \right|_{z=L} = \left. \frac{d\epsilon_B}{dz} \right|_{z=L} = 0. \quad (4.75)$$

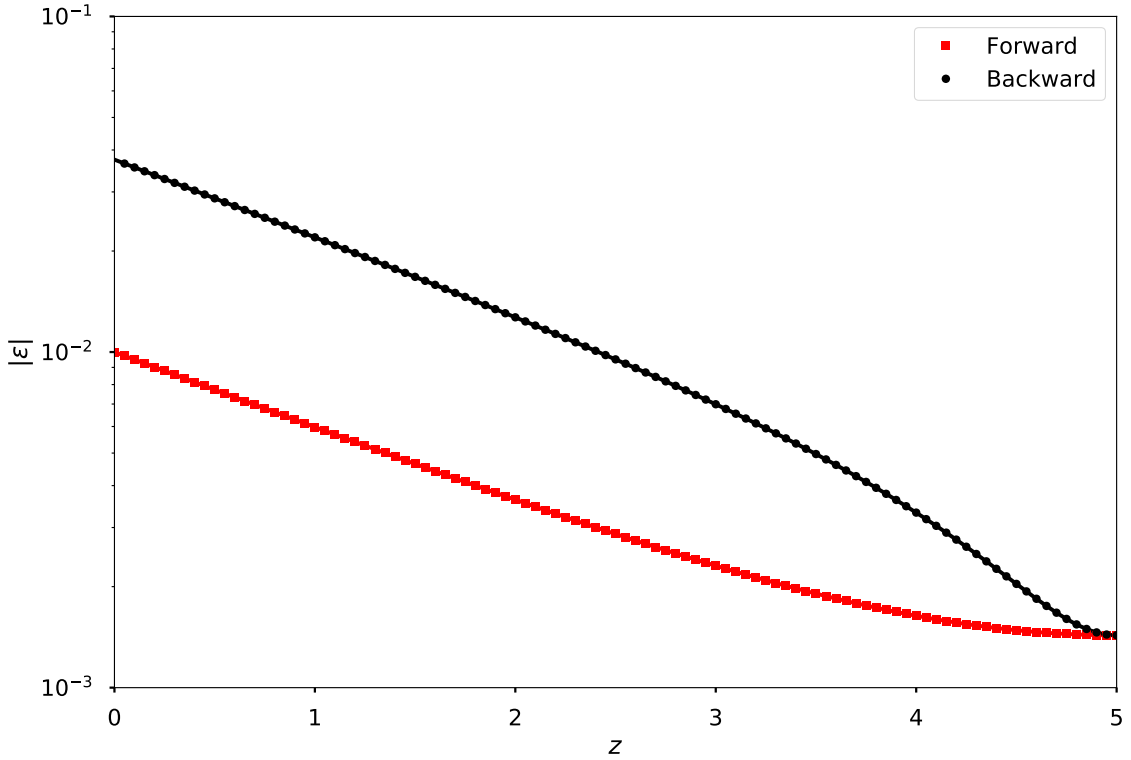

Figure 4.8: The magnitudes of the off-diagonal elements of the density matrices of the forward and reflected neutrino beams as functions of distance z , respectively. The markers are the numerical results for the single-beam model with $\mu' = 1.0$, $R = 0.07$, $L = 5/\omega_v$, and the normal hierarchy. The continuous curves are the analytical results obtained from Eqn. (4.71).

For small values of ϵ_F and ϵ_B , the solution from the linearized equation should represent the numerical calculations faithfully. In Fig. 4.8, I plotted the numerical result (dots) as well as the result from Eqn. (4.72) (lines). It clearly shows that the linearized solution is a great match to the numerical result. This is also a method to validate the code.

In Fig. 4.8, I compare the numerical results obtained from the relaxation algorithm

with the analytical results in Eqn. (4.71) for the single-beam model with $\mu' = 1.0$, $R = 0.07$, $L = 5/\omega_v$, and the normal hierarchy. The good agreement between these results shows that the numerical code works as expected.

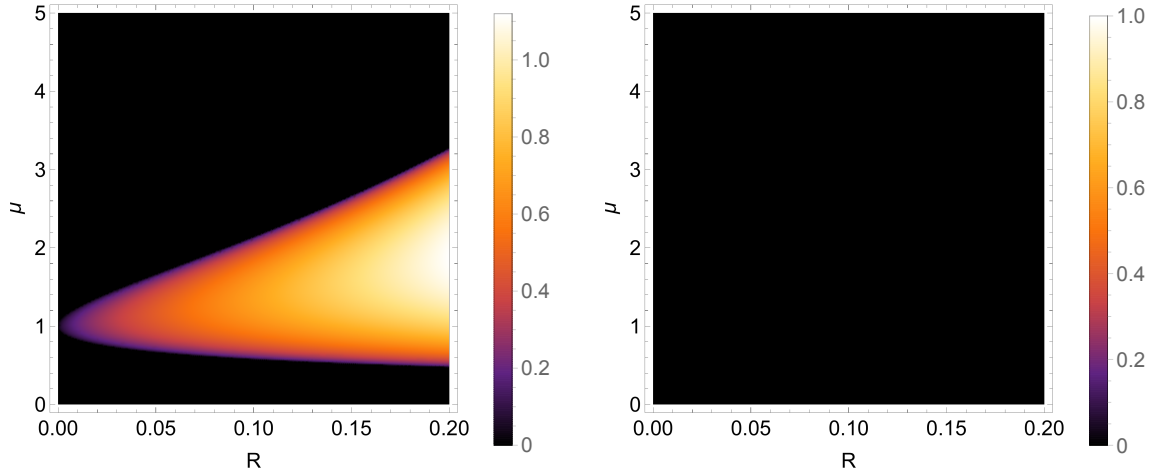

Figure 4.9: Instability regions for the normal hierarchy (left) and the inverted hierarchy (right) in the single-beam model with reflection. The color represents the magnitude of the imaginary component of the collective frequency.

Comparing Eqn. (4.19) and Eqn. (4.64), one sees that the single-beam model with reflection is equivalent to the two-beam model without reflection except that the reflected neutrino beam now plays the role of the antineutrino, $R \rightarrow \alpha$, $\eta \rightarrow -\eta$, and $\mu' \rightarrow \mu$. Therefore, flavor instabilities should exist for the normal mass hierarchy in the single-beam-model with reflection (see Fig. 4.9).

4.6 Summary

A dense neutrino medium can oscillate collectively because of the neutrino self-interaction potential. When the neutrino flavor conversion probabilities are small, one can apply the linearized flavor stability analysis to find out the regimes where neutrino oscillations begin to develop. I. Izaguirre et al. proposed that the flavor instabilities of a neutrino medium are associated with “gaps” between the real dis-

Chapter 4. Collective Neutrino Oscillations

persion relation curves of the collective modes. In this chapter, I have shown that this association is not valid in general. In particular, I showed that flavor instabilities can exist in three-beam models and in models with continuous but crossed ELN distributions without any gap in the real dispersion relation curves.

I proposed a toy model with two neutrino beams to explore neutrino oscillations with scattered fluxes such as in the supernova model with a neutrino halo. I have developed a relaxation method and a numerical code based on this method to solve this model, and I have validated the numerical code in the scenario where only the neutrino beam and its reflected beam exist.²

²The code can be accessed at <https://github.com/NeuPhysics/neutrino-halo-problem>.

Chapter 5

Conclusions and Future Work

Neutrinos are abundantly produced in astrophysical environments such as core-collapse supernovae and binary neutron star mergers. They play important roles in the chemical and physical evolutions of these environments. Since different neutrino flavors have different influence on the environments, identifying the neutrino fluxes in different flavors becomes important. Meanwhile, neutrinos oscillate between different flavors while they propagate through space due to the mismatch of the flavor states and the mass states. Therefore it is important to understand the flavor evolution of dense neutrino media.

The interactions between the neutrino and matter can cause the neutrino to experience flavor transformation through the so called MSW mechanism if the matter profile is smooth. Neutrinos can also experience parametric resonances when there exist oscillatory perturbations to a smooth profile of the matter density. In this dissertation, I showed that this parametric resonance behavior can be understood as Rabi oscillations which provides a simple yet intuitive picture to understand this interesting phenomenon. Interestingly, there exists an infinite number of Rabi modes even for a sinusoidal matter perturbation. I showed that most of these Rabi modes are irrelevant in a real physical system because of their tiny amplitudes, which is also true for multi-frequency matter profiles. I also derived a criterion which can be used to determine whether an off-resonance Rabi mode can significantly alter the behavior of the Rabi oscillation.

For future research, neutrino oscillations can be calculated with realistic matter

Chapter 5. Conclusions and Future Work

profiles in supernovae or stars. The criteria I have derived in my dissertation can be used to select the on-resonance and off-resonance Rabi modes that are important to neutrino flavor transformation and to identify the parametric resonances in these environments.

A dense neutrino medium can experience collective flavor oscillations because of the neutrino self-interaction. The linearized flavor stability analysis and the dispersion relations of the collective modes have been used to identify the physical regimes where collective oscillations may occur. In this dissertation, I applied these methods to the neutrino media with discrete and continuous angular emissions. I showed that, contrary to the conjecture by I. Izaguirre et al. in Ref. [37], the flavor instabilities of a neutrino medium are not necessarily associated with the gaps in the dispersion relation curves of the collective modes. More work needs to be done to understand the origin and nature of the flavor instabilities of a dense medium and their relation to the dispersion relations of the collective modes.

The problem of neutrino oscillations in supernovae is further complicated by the presence of the neutrino halo formed by scattered neutrino fluxes. In this dissertation, I have developed a toy model to explore neutrino oscillations in the presence of scattered neutrino fluxes. I have also developed a relaxation method and a parallel numerical code based on this algorithm to solve this toy model. More calculations need to be done to find out how the scattered neutrino fluxes may affect neutrino oscillations.
